Abstract

We present the first measurement of the weak phase $2\beta + \gamma$ obtained from a time-dependent (amplitude) analysis of $B_s^0 \rightarrow D_s K \pi \pi$ decays using proton-proton collision data corresponding to an integrated luminosity of **xxx** fb⁻¹ recorded by the LHCb detector.

1 Introduction

The weak phase γ is the least well known angle of the CKM unitary triangle. A key channel to measure γ is the time-dependent analysis of $B_s^0 \rightarrow D_s K$ decays [1], [2]. The $B_s^0 \rightarrow D_s K \pi \pi$ proceeds at tree level via the transitions shown in Fig. 1.1 a) and b).

Figure 1.1: Feynman diagram of the $B_s^0 \rightarrow D_s K \pi \pi$ decay, proceeding via a) $b \rightarrow c$ transitions or b) $b \rightarrow u$ transitions.

To measure the weak CKM phase $\gamma \equiv \arg[-(V_{ud}V_{ub}^*)/(V_{cd}V_{cb}^*)]$, a decay with interference between $b \rightarrow c$ and $b \rightarrow u$ transitions at tree level is needed [1]. As illustrated in Fig. 1.1, this is the case for the presented decay mode. A measurement of γ using $B_s^0 \rightarrow D_s K \pi \pi$ decays, where the $K \pi \pi$ subsystem is dominated by excited kaon states such as the $K_1(1270)$ and $K_1(1400)$ resonances, will succeed the branching ratio measurement presented in this note. It is complementary to the above mentioned analysis of $B_s^0 \rightarrow D_s K$, making use of a fully charged final state, where every track is detected in the vertex locator. To account for the non-constant strong phase across the Dalitz plot, one can either develop a time-dependent amplitude model or select a suitable phase-space region and introduce a coherence factor as additional hadronic parameter to the fit.

This analysis is based on the first observation of the $B_s^0 \rightarrow D_s K \pi \pi$ decay presented in [3] and [4], where its branching ratio is measured relative to $B_s^0 \rightarrow D_s \pi \pi \pi$. The result obtained by the previous analysis is $0.052 \pm 0.005 \pm 0.003$, where the uncertainties are statistical and systematical, respectively. The branching ratio measurement is updated, exploiting the full Run 1 data sample, corresponding to 3 fb^{-1} of integrated luminosity.

2 Sensitivity studies

2.1 PDF

First, I define the purely hadronic amplitudes for a given phasespace point x . The weak phase dependence is written latter explicitly in the pdf.

$$A(B_s^0 \rightarrow D_s^- K^+ \pi \pi) \equiv A(x) = \sum_i a_i A_i(x) \quad (2.1)$$

$$A(B_s^0 \rightarrow D_s^+ K^- \pi \pi) \equiv \bar{A}(\bar{x}) = \sum_i \bar{a}_i \bar{A}_i(\bar{x}) \quad (2.2)$$

$$A(\bar{B}_s^0 \rightarrow D_s^- K^+ \pi \pi) = \bar{A}(x) \text{ (Assuming no direct CPV)} \quad (2.3)$$

$$A(\bar{B}_s^0 \rightarrow D_s^+ K^- \pi \pi) = A(\bar{x}) \text{ (Assuming no direct CPV)} \quad (2.4)$$

The full time-dependent amplitude pdf is given by:

$$\begin{aligned} P(x, t, q_t, q_f) \propto & [(|A(x)|^2 + |\bar{A}(x)|^2) \cosh\left(\frac{\Delta\Gamma t}{2}\right) \\ & + q_t q_f (|A(x)|^2 - |\bar{A}(x)|^2) \cos(m_s t) \\ & - 2\text{Re}(A(x)^* \bar{A}(x) e^{-iq_f(\gamma-2\beta_s)}) \sinh\left(\frac{\Delta\Gamma t}{2}\right) \\ & - 2q_t q_f \text{Im}(A(x)^* \bar{A}(x) e^{-iq_f(\gamma-2\beta_s)}) \sin(m_s t)] e^{-\Gamma t} \end{aligned}$$

where $q_t = +1$ (-1) for a B_s^0 (\bar{B}_s^0) tag and $q_f = +1$ (-1) for $D_s^- K^+ \pi \pi$ ($D_s^+ K^- \pi \pi$) final states.

Integrating over the phasespace, we get

$$\begin{aligned} \int P(x, t, q_t, q_f) dx \propto & [\cosh\left(\frac{\Delta\Gamma t}{2}\right) \\ & + q_t q_f \left(\frac{1-r^2}{1+r^2}\right) \cos(m_s t) \\ & - 2 \left(\frac{\kappa r \cos(\delta - q_f(\gamma - 2\beta_s))}{1+r^2}\right) \sinh\left(\frac{\Delta\Gamma t}{2}\right) \\ & - 2q_t q_f \left(\frac{\kappa r \sin(\delta - q_f(\gamma - 2\beta_s))}{1+r^2}\right) \sin(m_s t)] e^{-\Gamma t} \\ = & [\cosh\left(\frac{\Delta\Gamma t}{2}\right) + q_t q_f C \cos(m_s t) - \kappa D_{q_f} \sinh\left(\frac{\Delta\Gamma t}{2}\right) - q_t \kappa S_{q_f} \sin(m_s t)] e^{-\Gamma t} \end{aligned}$$

where the C, D_{q_f}, S_{q_f} are defined exactly as for $D_s K$. The coherence factor is defined as :

$$\kappa e^{i\delta} \equiv \frac{\int A(x)^* \bar{A}(x) dx}{\sqrt{\int |A(x)|^2 dx} \sqrt{\int |\bar{A}(x)|^2 dx}} \quad (2.5)$$

$$r \equiv \frac{\sqrt{\int |\bar{A}(x)|^2 dx}}{\sqrt{\int |A(x)|^2 dx}} \quad (2.6)$$

and appears in front of the D_{q_f}, S_{q_f} terms. This means one additional fit parameter for the lifetime fit. In the limit of only one contributing resonance $\kappa \rightarrow 1$.

2.2 Estimation of coherence factor

To estimate the coherence factor we could generate many toys with random a_i and \bar{a}_i values (see https://twiki.cern.ch/twiki/pub/LHCbPhysics/Bu2DKstar/LHCb-ANA-2017-005_v1.pdf) using the set of amplitudes show in our last talk. However with so many interfering amplitudes, I would be surprised if you couldn't generate every possible value for κ . In any case, this would give us a range where to expect possible values for κ . Worst case would be $0 \leq \kappa \leq 1$.

Assumptions:

- $A(x) = \sum_i a_i A_i(x)$
 $\bar{A}(x) = \sum_i \bar{a}_i \bar{A}_i(x)$
- Use amplitudes from flavor-averaged, time-integrated fit
- Draw random a_i and \bar{a}_i values
- Constraints:
 $\int (|a_i A_i(x)|^2 + |\bar{a}_i \bar{A}_i(x)|^2) dx / N = F_i^{eff}$
 $r \approx 0.4$ (ration of CKM elements)

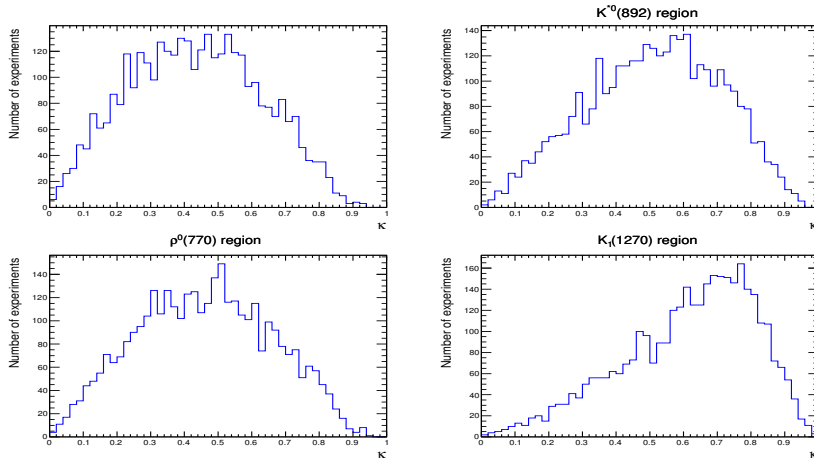

Figure 2.1

2.3 Results

Assumptions:

- Use amplitudes from flavor-averaged, time-integrated fit
- $r = 0.4$ (ratio of CKM elements)
- PDG values for: $\tau, \Delta m_s, \Delta \Gamma, \beta_s$
- $\epsilon(x, t) = \text{const.}$, perfect resolution
- $\epsilon_{Tag} = 0.66, < \omega > = 0.4$
- $N_{signal} = 3000$ (Run1+15/16 data)

Figure 2.2: Example toy fit

Generated values:

$$\gamma = 70^\circ, \delta = 100^\circ$$

Fit result:

$$\gamma = 74 \pm 15^\circ, \delta = 84 \pm 15^\circ$$

$$(\gamma = 254 \pm 15^\circ, \delta = 264 \pm 15^\circ)$$

3 Selection

For the presented analysis, we reconstruct the $B_s^0 \rightarrow D_s K \pi \pi$ decay through three different final states of the D_s meson, $D_s \rightarrow K K \pi$, $D_s \rightarrow K \pi \pi$ and $D_s \rightarrow \pi \pi \pi$. Of those three final states $D_s \rightarrow K K \pi$ is the most prominent one, while $\mathcal{BR}(D_s \rightarrow \pi \pi \pi) \approx 0.2 \cdot \mathcal{BR}(D_s \rightarrow K K \pi)$ and $\mathcal{BR}(D_s \rightarrow K \pi \pi) \approx 0.1 \cdot \mathcal{BR}(D_s \rightarrow K K \pi)$ holds for the other two.

A two-fold approach is used to isolate the $B_s^0 \rightarrow D_s K \pi \pi$ candidates from data passing the stripping line. First, further one-dimensional cuts are applied to reduce the level of combinatorial background and to veto some specific physical background. This stage is specific to the respective final state in which the D_s meson is reconstructed, since different physical backgrounds, depending on the respective final state, have to be taken into account. After that, a multivariate classifier is trained which combines the information of several input variables, including their correlation, into one powerful discriminator between signal and combinatorial background. For this stage, all possible D_s final states are treated equally.

3.1 Cut-based selection

In order to minimize the contribution of combinatorial background to our samples, we apply the following cuts to the b hadron:

- $\text{DIRA} > 0.99994$
- $\min \text{IP } \chi^2 < 20$ to any PV,
- $\text{FD } \chi^2 > 100$ to any PV,
- $\text{Vertex } \chi^2/\text{nDoF} < 8$,
- $(Z_{D_s} - Z_{B_s^0}) > 0$, where Z_M is the z-component of the position \vec{x} of the decay vertex for the B_s^0/D_s meson.

Additionally, we veto various physical backgrounds, which have either the same final state as our signal decay, or can contribute via a single misidentification of $K \rightarrow \pi$ or $K \rightarrow p$. In the following, the vetoes are ordered by the reconstructed D_s final state they apply to:

1. All:

- (a) $B_s^0 \rightarrow D_s^+ D_s^- : |M(K \pi \pi) - m_{D_s}| > 20 \text{ MeV}/c^2$.
- (b) $B_s^0 \rightarrow D_s^- K^+ K^- \pi^+ : \text{possible with single missID of } K^- \rightarrow \pi^-$, rejected by requiring π^- to fulfill $\text{DLL}_{K\pi} < 5$.

2. $D_s \rightarrow K K \pi$

- (a) $B^0 \rightarrow D^+(\rightarrow K^+ \pi^- \pi^+) K \pi \pi : \text{possible with single missID of } \pi^+ \rightarrow K^+$, vetoed by changing particle hypothesis and recompute $|M(K^+ \pi^- \pi^+) - m_{Dp}| > 30 \text{ MeV}/c^2$, or the K^+ has to fulfill $\text{DLL}_{K\pi} > 10$.

(b) $\Lambda_b^0 \rightarrow \Lambda_c^+(\rightarrow pK^-\pi^+)K\pi\pi$: possible with single missID of $p \rightarrow K^+$, vetoed by changing particle hypothesis and recompute $M(pK^-\pi^+) - m_{\Lambda_c^+} > 30 \text{ MeV}/c^2$, or the K^+ has to fulfill $(\text{DLL}_{K\pi} - \text{DLL}_{p\pi}) > 5$.

(c) $D^0 \rightarrow KK$: D^0 combined with a random π can fake a $D_s \rightarrow KK\pi$ decay and be a background to our signal, vetoed by requiring $M(KK) < 1840 \text{ MeV}/c^2$.

3. $D_s \rightarrow K\pi\pi$

(a) $D^0 \rightarrow \pi^+K^-$: D^0 combined with a random π^- can fake a $D_s^- \rightarrow K^-\pi^+\pi^-$ decay and be a background to our signal, vetoed by requiring $M(\pi^+K^-) < 1750 \text{ MeV}/c^2$.

(b) $\Lambda_b^0 \rightarrow \Lambda_c^+(\rightarrow p\pi^-\pi^+)K\pi\pi$: possible with single missID of $p \rightarrow K^+$, vetoed by changing particle hypothesis and recompute $M(p\pi^-\pi^+) - m_{\Lambda_c^+} > 30 \text{ MeV}/c^2$, or the K^+ has to fulfill $(\text{DLL}_{K\pi} - \text{DLL}_{p\pi}) > 5$.

4. $D_s \rightarrow \pi\pi\pi$

(a) $D^0 \rightarrow \pi\pi$: combined with a random π can fake a $D_s \rightarrow \pi\pi\pi$ decay and be a background to our signal, vetoed by requiring both possible combinations to have $M(\pi\pi) < 1700 \text{ MeV}/c^2$.

The most prominent final state used in this analysis is $B_s^0 \rightarrow D_s(\rightarrow KK\pi)K\pi\pi$, where the D_s decay can either proceed via the narrow ϕ resonance, the broader K^{*0} resonance, or non resonant. Depending on the decay process being resonant or not, we apply additional PID requirements on this final state:

- resonant case:

- $D_s^+ \rightarrow \phi\pi^+$, with $|M(K^+K^-) - m_\phi| < 20 \text{ MeV}/c^2$: no additional requirements, since ϕ is narrow and almost pure K^+K^- .
- $D_s^+ \rightarrow \bar{K}^{*0}K^+$, with $|M(K^-\pi^+) - m_{K^{*0}}| < 75 \text{ MeV}/c^2$: $\text{DLL}_{K\pi} > 0$ for kaons, since this resonance is more than ten times broader than ϕ .

- non resonant case: $\text{DLL}_{K\pi} > 5$ for kaons, since the non resonant category has significant charmless contributions.

For the other two final states, we apply global PID requirements:

- $D_s \rightarrow K\pi\pi$

- $\text{DLL}_{K\pi} > 10$ for kaons, since we expect significantly higher charmless background contribution in this channel.
- $\text{DLL}_{K\pi} < 5$ for pions.

- $D_s \rightarrow \pi\pi\pi$

- $\text{DLL}_{K\pi} < 10$ for all pions.
- $\text{DLL}_{p\pi} < 10$ for all pions.

3.2 Multivariate stage

We use TMVA [5] to train a multivariate discriminator, which is used to further improve the signal to background ratio. The 17 variables used for the training are:

- $\max(\text{ghostProb})$ over all tracks
- $\text{cone}(p_T)$ asymmetry of every track, which is defined to be the difference between the p_T of the π/K and the sum of all other p_T in a cone of radius $r = \sqrt{(\Delta\Phi)^2 + (\Delta\eta)^2} < 1$ rad around the signal π/K track.
- $\min(\text{IP}\chi^2)$ over the X_s daughters
- $\max(\text{DOCA})$ over all pairs of X_s daughters
- $\min(\text{IP}\chi^2)$ over the D_s daughters
- D_s and B_s^0 DIRA
- D_s FD significance
- $\max(\cos(D_s h_i))$, where $\cos(D_s h_i)$ is the cosine of the angle between the D_s and another track i in the plane transverse to the beam
- B_s^0 $\text{IP}\chi^2$, $\text{FD}\chi^2$ and Vertex χ^2

Various classifiers were investigated in order to select the best performing discriminator. Consequently, a boosted decision tree with gradient boost (BDTG) is chosen as nominal classifier. We use truth-matched MC as signal input. Simulated signal candidates are required to pass the same trigger, stripping and preselection requirements, that were used to select the data samples. For the background we use events from the high mass sideband ($m_{B_s^0 \text{ candidate}} > 5600 \text{ MeV}/c^2$) of our data samples. As shown in Fig. 3.1, this mass region is sufficiently far away from signal structures and is expected to be dominantly composed of combinatorial background.

The distributions of the input variables for signal and background are shown in Fig. 3.2.

The relative importance of the input variables for the BDTG training is summarized in Table 4.1.

The BDTG output distribution for test and training samples is shown in Fig 3.3. No sign of overtraining is observed.

We determine the optimal cut value by maximizing the figure of merit $S/\sqrt{S+B}$ where S is the signal yield and B the background yield in the signal region, defined to be within $\pm 50 \text{ MeV}/c^2$ of the nominal B_s^0 mass. To avoid a bias in the determination of the branching fraction, we determine S and B using our normalization channel. All trigger, stripping and additional selection criteria described in this and the previous chapter are applied to the $B_s^0 \rightarrow D_s \pi \pi \pi$ data samples. After that, we perform a simplified version of the fit to the invariant mass distribution of $B_s^0 \rightarrow D_s \pi \pi \pi$ candidates described in Sec. ???. Here, a Gaussian function to model the signal and an exponential function to model combinatorial background is used. From this fit we estimate the number of signal events

Figure 3.1: Invariant mass distribution of preselected $B_s^0 \rightarrow D_s K \pi \pi$ candidates. The red coloured region with $m_{B_s^0 \text{ candidate}} > 5600 \text{ MeV}/c^2$ is used as background input for the boosted decision tree.

Table 3.1: Summary of the relative importance of each variable in the training of the BDTG.

189 in our normalization channel. Multiplying that number with the PDG branching fraction
190 of $\frac{\mathcal{B}(B_s^0 \rightarrow D_s K \pi \pi)}{\mathcal{B}(B_s^0 \rightarrow D_s \pi \pi \pi)}$ and the ratio of efficiencies discussed in Sec. ?? allows us to estimate the
191 expected number of $B_s^0 \rightarrow D_s K \pi \pi$ signal decays. The number of background events can
192 then be computed as

$$N_{bkg} = N_{all} - N_{sig}|_{m_{B_s^0} \pm 50 \text{ MeV}/c^2}. \quad (3.1)$$

Figure 3.2: Distributions of the input variables used in the BDTG training. The background is shown as red hatched, while the signal is depicted solid blue.

The efficiency curves as a function of the cut value are shown in Fig. 3.4. The optimal cut value is found to be $\text{BDTG} > 0.7012$. At this working point the signal efficiency is estimated to be 72.47 %, while the background rejection in the signal region is 97.38 %.

Figure 3.4: Efficiency and purity curves for (blue) signal, (red) background and the (green) FoM curve, as a function of the chosen cut value.

4 Decay-time Acceptance

The decay-time distribution of the B_s^0 mesons is sculpted due to the geometry of the LHCb detector and the applied selection cuts, which are described in Section 3. In particular, any requirement on the flight distance (FD), the impact parameter (IP) or the direction angle (DIRA) of the B_s^0 mesons, as well as the direct cut on the lifetime, will lead to a decay-time dependent efficiency $a(t)$. This efficiency will distort the theoretically expected, time-dependent decay rate

$$\frac{\Gamma(t)^{observed}}{dt} = \frac{\Gamma(t)^{theory}}{dt} \cdot a(t), \quad (4.1)$$

and has to be modelled correctly, in order to describe the observed decay rate. We use our control channel for this measurement, because for $B_s^0 \rightarrow D_s K \pi \pi$ decays the decay-time acceptance is correlated with the CP-observables which we aim to measure. Therefore, floating the CP-observables and the acceptance shape at the same time is not possible. Hence, a fit to the decay-time distribution of $B_s^0 \rightarrow D_s \pi \pi \pi$ candidates is performed and the obtained acceptance shape is corrected by the difference in shape found for the $B_s^0 \rightarrow D_s K \pi \pi$ and $B_s^0 \rightarrow D_s \pi \pi \pi$ MC.

A PDF of the form

$$\mathcal{P}(t', \vec{\lambda}) = \left[(e^{\Gamma_s t} \cdot \cosh(\frac{\Delta \Gamma_s t}{2}) \times \mathcal{R}(t - t')) \cdot \epsilon(t', \vec{\lambda}), \quad (4.2)$$

is fit to the decay time distribution of $B_s^0 \rightarrow D_s \pi \pi \pi$ candidates in data. Since the fit is performed untagged, the PDF shown in Eq. 4.2 contains no terms proportional to Δm_s . The values for Γ_s and $\Delta \Gamma_s$ are fixed to the latest HFAG results [6]. The decay-time acceptance $\epsilon(t', \vec{\lambda})$ is modelled using the sum of cubic polynomials $v_i(t)$, so called Splines [7]. The polynomials are parametrised by so-called knots which determine their boundaries. Knots can be set across the fitted distribution to account for local changes in the acceptance shape. Using more knots is equivalent to using more base splines which are defined on a smaller sub-range. In total, $n + 2$ base splines $v_i(t)$ are needed to describe an acceptance shape which is parametrised using n knots.

For fits shown in the following, the knots have been placed at $t = [0.5, 1.0, 1.5, 2.0, 3.0, 9.5] ps$. To accomodate these 6 knot positions, 8 basic splines v_i , $i = [1, \dots, 8]$ are used. Since a rapid change of the decay time acceptance at low decay times due to the turn-on effect generated by the lifetime and other selection cuts is expected, more knots are placed in that regime. At higher decay times we expect linear behaviour, with a possible small effect due to the VELO reconstruction. Therefore fewer knots are used. Furthermore, v_7 is fixed to 1 in order to normalize the overall acceptance function. To stabilise the last spline, v_8 is fixed by a linear extrapolation from the two previous splines:

$$v_N = v_{N-1} + \frac{v_{N-2} - v_{N-1}}{t_{N-2} - t_{N-1}} \cdot (t_N - t_{N-1}). \quad (4.3)$$

Here, $N = 8$ and t_{N-1} corresponds to the knot position associated with v_{N-1} . The nominal fit to $B_s^0 \rightarrow D_s \pi \pi \pi$ data using this configuration is shown in Figure 4.1. Note that the normalization of the splines in the following figures is not in scale.

The fits to $B_s^0 \rightarrow D_s \pi \pi \pi$ and $B_s^0 \rightarrow D_s K \pi \pi$ simulation are shown in Figure 4.2.

Figure 4.1: Decay-time distribution of $B_s^0 \rightarrow D_s \pi \pi \pi$ candidates for the Run 1 data sample. The fit described in the text is overlaid. The red line shows the spline function describing the acceptance and the blue line depicts the total fit function.

Figure 4.2: Decay-time distribution of (left) $B_s^0 \rightarrow D_s \pi \pi \pi$ and (right) $B_s^0 \rightarrow D_s K \pi \pi$ candidates in MC using truth information. The fit described in the text is overlaid. The red line shows the spline function describing the acceptance and the blue line depicts the total fit function.

233 The fit parameters obtained from the described fits to data and simulation are
