Abstract

We present the measurement of the branching fraction of decay $B_s^0 \to D_s K\pi\pi$ using the complete 3 fb^{-1} of data, collected during Run 1 of the LHC. The branching fraction is measured relative to the decay $B_s^0 \to D_s\pi\pi\pi$, from which we obtain

$$\frac{\mathcal{B}(B_s^0 \to D_s K\pi\pi)}{\mathcal{B}(B_s^0 \to D_s\pi\pi\pi)} = xx \pm xx \pm xx$$

The $B_s^0 \to D_s K\pi\pi$ decay can be further used to measure the weak CKM phase γ in a time-dependent analysis of the B_s^0 and $\overline{B}{}_s^0$ decay rates.

1 Introduction

The weak phase γ is the least well known angle of the CKM unitary triangle. A key channel to measure γ is the time-dependent analysis of $B_s^0 \to D_s K$ decays [REF HERE]. The measurement of γ presented in this note uses $B_s^0 \to D_s K\pi\pi$ decays, where the $K\pi\pi$ subsystem is dominated by excited kaon states, such as the $K_1(1270)$ and $K_1(1400)$ resonances. It is complementary to the above mentioned analysis of $B_s^0 \to D_s K$, making use of a fully charged final state, where every track is detected in the vertex locator. To account for the non-constant strong phase across the Dalitz plot, one can either develop a time-dependent amplitude model or select a suitable phase-space region and introduce a coherence factor as additional hadronic parameter to the fit.
This analysis is based on the first observation of the $B_s^0 \to D_s K\pi\pi$ decay presented in [1] and [2], where its branching ratio is measured relative to $B_s^0 \to D_s \pi\pi\pi$. The branching ratio measurement is updated , exploiting the full Run 1 data sample, corresponding to 3 fb^{-1} of integrated luminosity.

2 Data samples

We use the full Run 1 sample from Stripping 21, consisting of 3 fb^{-1} of data, collected in the years 2011 and 2012 at a center of mass energies of 7 TeV and 8 TeV, respectively. The selected B_s^0-candidates are required to pass the L0 Hadron trigger on signal (TOS) or the L0 Global trigger independent of signal (TIS).
Events that pass the L0 stage are further required to pass the HLT1 TrackAllL0 trigger on signal (TOS).
All remaining candidates have to pass either the 2, 3 or 4-body topological trigger (TOS) of the HLT2 stage.
For the presented analysis the B02DKPiPiD2HHHPIDBeauty2CharmLine is used to preselect signal $B_s^0 \to D_s K\pi\pi$ candidates. A summary of the cuts employed by this stripping line can be found in Table 2.1. In this table and throughout the note, we abbreviate $B_s^0 \to D_s X_s(\to K\pi\pi)$ and $B_s^0 \to D_s X_d(\to \pi\pi\pi)$, identifying $X_s \to K\pi\pi$ and $X_d \to \pi\pi\pi$ as the various resonances through which the decays proceed.

4 Selection

A twofold approach is used to isolate the $B_s^0 \to D_s K\pi\pi$ candidates from data passing the stripping line. First, further one-dimensional cuts are applied to reduce the level of combinatorial background and to veto some specific physical background. After that, a

Variable	Stripping Cut
Track χ^2/nDoF	< 3
Track p	> 1000 MeV/c
Track p_{T}	> 100 MeV/c
Track IP χ^2	> 4
D_s Daughter p_{T}	$\Sigma_{i=1}^{3} p_i > 1800\,\mathrm{MeV}/c$
D_s Daughter DOCA	0.5 mm
D_s mass m_{D_s}	within $\pm$ 40 MeV/c^2 of PDG value
D_s Vertex chi^2/nDoF	< 10
D_s min FD chi^2	> 36
X_d Daughter p_{T}	> 2 GeV/c
$X_{s,d}$ Daughter DOCA	0.4 mm
$X_{s,d}$ Daughter p_{T}	$\Sigma_{i=1}^{3} p_{t,i} > 1250\,\mathrm{MeV}/c$
$X_{s,d}$ Vertex chi^2/nDoF	< 8
$X_{s,d}$ min FD chi^2/nDoF	> 16
$X_{s,d}$ DIRA	> 0.98
$X_{s,d}$ $\Delta\rho$ (vertex displacement perpendicular to z-axis)	> 0.1 mm
$X_{s,d}$ ΔZ (vertex displacement along z-axis)	> 2.0 mm
B_s^0 DIRA	> 0.98
B_s^0 min IP χ^2	> 25
B_s^0 Vertex chi^2/nDoF	< 10
B_s^0 $\tau_{B_s^0}$	> 0.2 ps
K DLL$_{K\pi}$	$>$ -5
π DLL$_{K\pi}$	< 10

Table 2.1: Summary of the stripping selections for $B_s^0 \to D_s K\pi\pi$ decays.

multivariate classifier is trained which combines the information of several input variables, including their correlation, into one powerful discriminator between signal and combinatorial background.

4.1 Cut-based selection

In order to minimize the contribution of combinatorial background to our samples, we apply the following cuts to the b-hadron:

(i) DIRA > 0.99994

(ii) min IP $\chi^2 < 20$ to any PV

(iii) FD $\chi^2 > 100$ to any PV

(iv) Vertex χ^2/nDoF < 8

(v) $(Z_{D_s} - Z_{B_s^0}) > 0$, where Z_M is the z-component of the position $\vec{x}$ of the decay vertex for the B_s^0/D_s meson

Additionally, we veto various physical backgrounds, which have either the same final state as our signal decay, or can contribute via a single miss-identification of $K \to \pi$ or $K \to p$:

- $B_s^0 \to D_s^+ D_s^-$: $|M(K\pi\pi) - m_{D_s}| > 20\,\mathrm{MeV}/c^2$
- $B_s^0 \to D_s K K \pi$: π^- $\mathrm{DLL}_{K\pi} < 5$ i
- $B^0 \to D^+(\to K^+\pi^-\pi^+)K\pi\pi$: possible with single miss-ID of $K^+ \to \pi^+$, vetoed by changing mass hypothesis and recompute $|M(K^+\pi^-\pi^+) - m_{Dp}| > 20$ MeV/c^2, or the K^+ has to fulfill $\mathrm{DLL}_{K\pi} > 10$
- $\Lambda_b^0 \to \Lambda_c^+(\to pK^-\pi^+)K\pi\pi$: possible with single miss-ID of $K^+ \to p$, vetoed by changing mass hypothesis and recompute $M(pK^-\pi^+) - m_{\Lambda_c^+} > 15$ MeV/c^2, or the K^+ has to fulfill $\mathrm{DLL}_{Kp} > 0$

All signal candidates for the branching ratio measurement are reconstructed via the $D_s \to K^+K^-\pi^+$ channel. This decay can either proceed via the narrow ϕ resonance, the broader K^{*0} resonance, or non-resonant. Depending on the decay process being resonant or not, we apply additional PID requirements:

1. resonant case, no additional PID requirements {In case of K^{*0} we also apply tighter PID cuts}:
   (a) $D_s^+ \to \phi\pi^+$, with $|M(K^+K^-) - m_\phi| < 20$ MeV/c^2
   (b) $D_s^+ \to \overline{K}^{*0}K^+$, with $|M(K^-\pi^+) - m_{K^{*0}} < 75$ MeV/c^2
2. non-resonant case: $\mathrm{DLL}_{K\pi} > 0$ for kaons

4.2 Multivariate stage

We use TMVA [3] to train a multivariate discriminator, which is used to further improve the signal to background ratio. The 17 variables used for the training are:

- max(ghostProb) over all tracks
- cone(p_T) asymmetry of every track
- min(IPχ^2) over the X_s daughters
- max(DOCA) over all pairs of X_s daughters
- min(IPχ^2) over the D_s daughters

- D_s DIRA
- D_s FD significance
- $\max(\cos(D_s h_i))$, where $\cos(D_s h_i)$ is the cosine of the angle between the D_s and another track i in the plane transverse to the beam
- B_s^0 IPχ^2, FDχ^2 and Vertex χ^2

Various classifiers were investigated in order to select the most efficient discriminator. As the result a boosted decision tree with gradient boost (BDTG) is chosen as nominal classifier. We use truth-matched Monte Carlo (MC) as signal input. Those simulated signal candidates are required to pass the same trigger and stripping requirements, that were used to select the data samples. {What about other preselection cuts? Maybe we could include the PID weights?} For the background we use events from the high mass sideband ($m_{B_s^0 candidate} > 5600$ MeV/c^2) of our data samples.
The distributions of the input variables for signal and background are shown in Fig. 4.1.

The relative importance of the input variables for the BDTG training is summarized in Table 4.1.

Table 4.1: Summary of the relative importance of each variable in the training of the BDTG.

The BDTG output distribution for test and training samples is shown in Fig 4.2. No sign of overtraining is observed.

We determine the optimal cut value by maximizing the figure of merit $S/\sqrt{S+B}$ where S is the signal yield and B the background yield in the signal region, defined to be

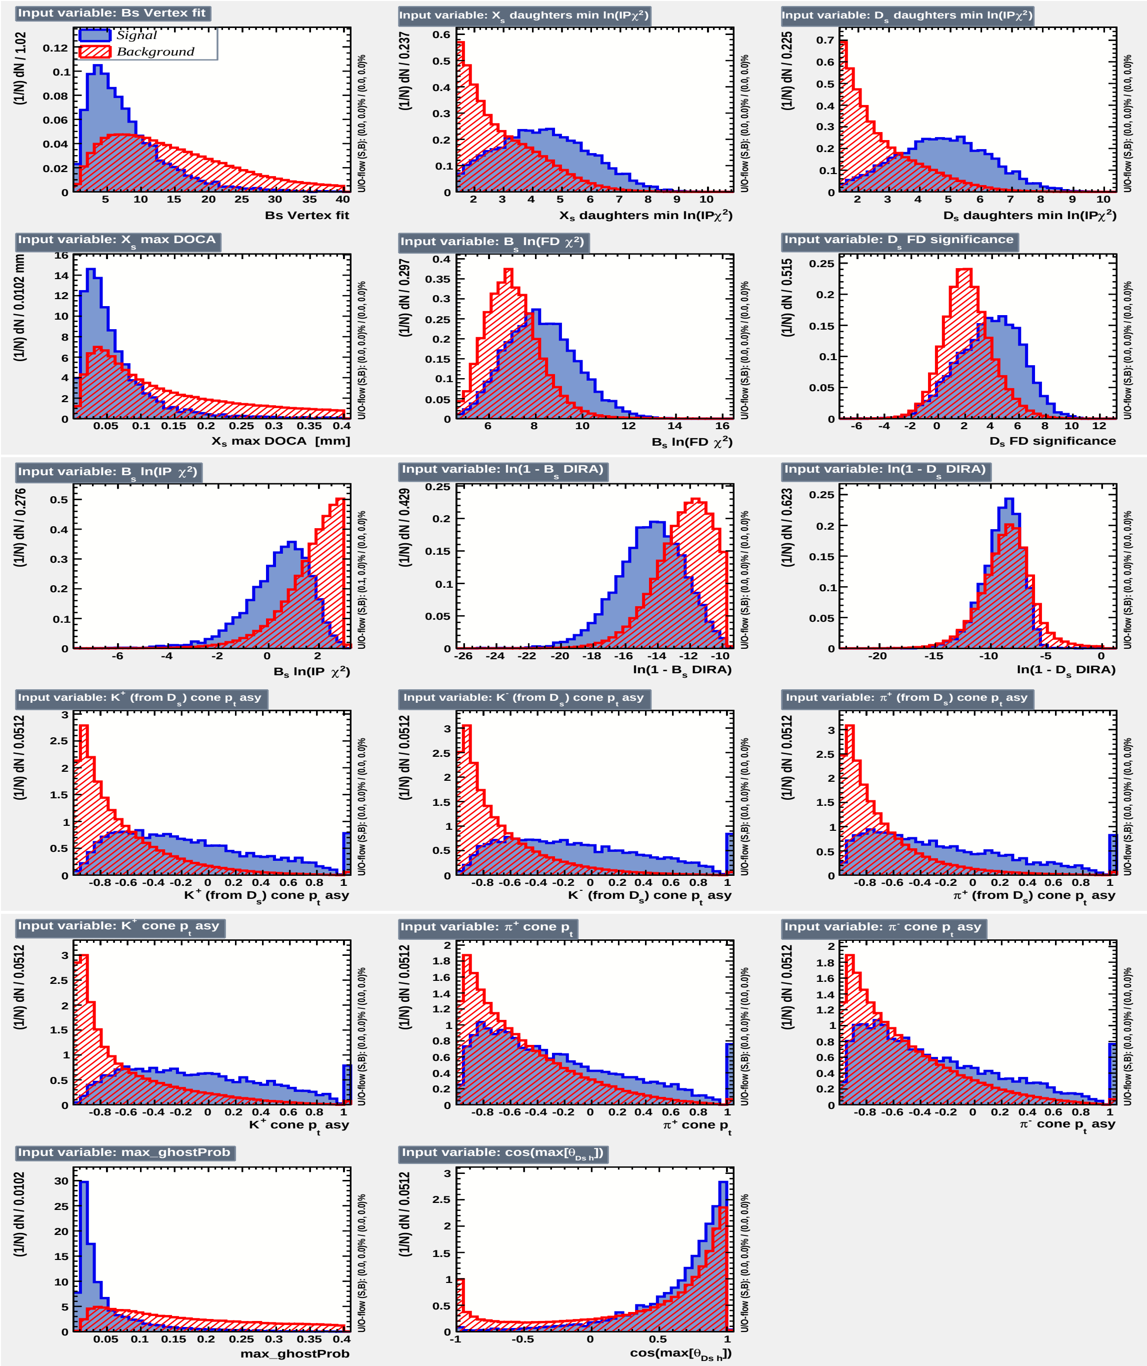

Figure 4.1: Distributions of the input variables used in the BDTG training. The background is shown as red hatched, while the signal is depicted solid blue.

within ± 50 MeV/c^2 of the nominal B_s^0 mass. To avoid a bias in the determination of the branching fraction, we determine S and B using our normalization channel. All trigger, stripping and additional selections described in this and the previous chapters are applied

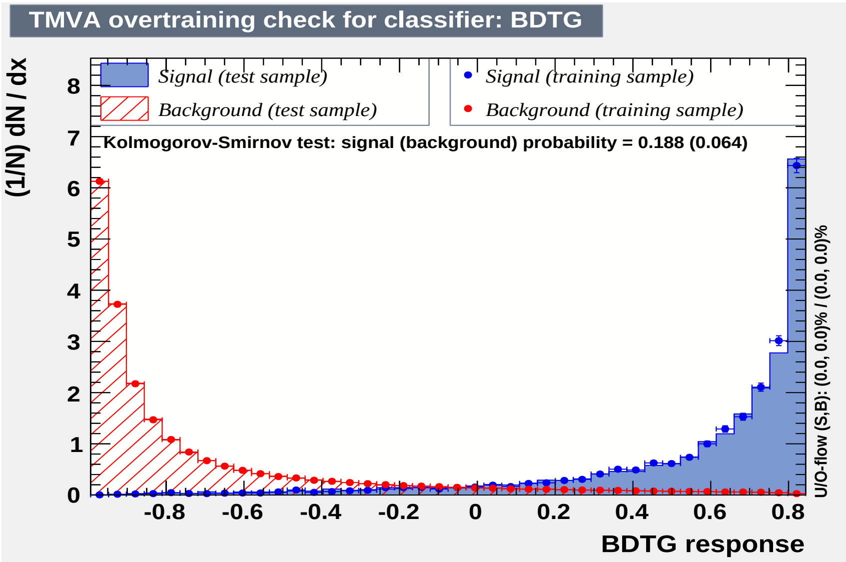

Figure 4.2: BDTG output classifier distribution for (blue) signal and (red) background. The response of an independent test sample is overlaid.

to the $B_s^0 \to D_s\pi\pi\pi$ data samples. After that, we perform a simplified version of the fit to the invariant mass distribution of $B_s^0 \to D_s\pi\pi\pi$ candidates described in Sec. 6. Here, a gaussian signal model and an exponential function to model combinatorial background is used. From this fit we can estimate the number of signal events in our normalization channel. Multiplying that number with the PDG branching fraction of $\frac{\mathcal{B}(B_s^0 \to D_s K\pi\pi)}{\mathcal{B}(B_s^0 \to D_s\pi\pi\pi)}$ and the ratio of efficiencies discussed in Sec. 7 allows us to estimate the expected number of $B_s^0 \to D_s K\pi\pi$ signals. The number of background events can then be computed as

$$N_{bkg} = N_{all} - N_{sig}|_{m_{B_s^0} \pm 50\,\mathrm{MeV}/c^2}. \tag{4.1}$$

The efficiency curves as a function of the cut value are shown in Fig. 4.3.

5 Models for signal and background components in invariant mass spectrum

The expected Signal shape, as well as the expected shape for the combinatorial and physical backgrounds have to be known in order to properly describe the invariant mass distribution of $B_s^0 \to D_s K\pi\pi$ and $B_s^0 \to D_s\pi\pi\pi$ candidates.

5.1 Signal model

The mass distribution of $B_s^0 \to D_s K\pi\pi$ signal is modeled using two gaussian functions, which share the same mean μ, but are allowed to have different widths σ_1 and σ_2. Another

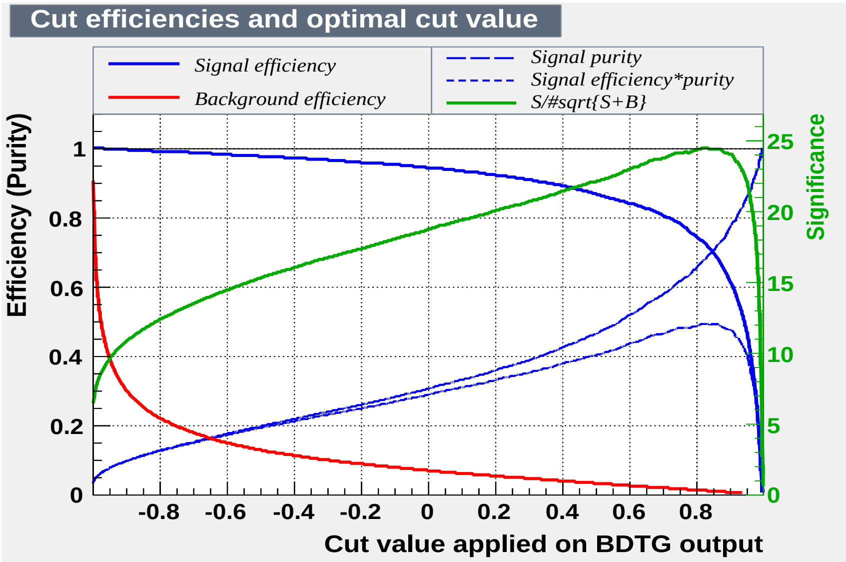

Figure 4.3: Efficiency and purity curves for (blue) signal, (red) background and the (green) FoM curve, as a function of the chosen cut value.

double gaussian is used to account for the contribution of $B^0 \to D_s K\pi\pi$ decays, which are also present in the $m(D_s K\pi\pi)$ spectrum. All parameters of both double gaussians except the core width σ_1 {Why is it fixed and to what? } are allowed to float in the nominal fit. The same approach is used to describe the invariant mass distribution of $B_s^0 \to D_s\pi\pi\pi$ candidates. A double gaussian is used to model this signal shape, all parameters except the core width σ_1 are allowed to float.

5.2 Background models for m($D_s\pi\pi\pi$)

Different background sources arise in the invariant mass spectrum of candidates for the normalization mode.
The following backgrounds have to be accounted for:

- combinatorial background: This contribution arises from either a real D_s, which is paired with random tracks to form the B_s^0 candidates, or via real X_d's, which are combined with three tracks that fake a D_s candidate to form a fake B_s^0.
- Partially reconstructed $B_s^0 \to D_s{}^*\pi\pi\pi$ decays, with $D_s{}^* \to D_s\gamma$ or $D_s{}^* \to D_s\pi^0$, where the γ/π^0 is not reconstructed in the decay chain.

In both cases of combinatorial background, the distribution in the invariant mass spectrum of B_s^0 candidates is expected to be smooth and decrease with higher masses. Therefore, one exponential function is used to model these contributions.
The shape of the $B_s^0 \to D_s{}^*\pi\pi\pi$ contribution is expected to be peaking in the $m(D_s\pi\pi\pi)$

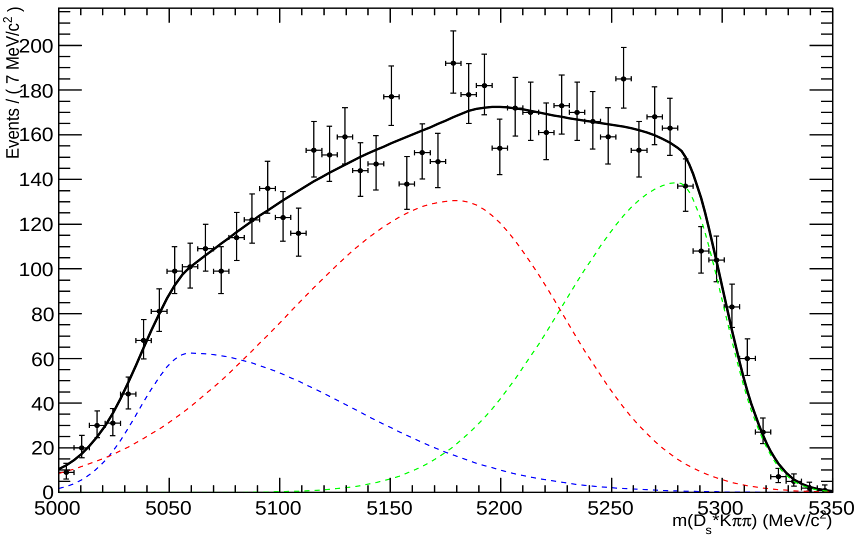

Figure 5.1: Invariant mass distribution of simulated $B_s^0 \to {D_s}^* \pi\pi\pi$ events, where the γ/π^0 is excluded from the reconstruction. A fit of the sum of three bifurcated gaussians to this distribution is overlaid.

spectrum, with large tails due to the missing momentum, which is carried away by the π^0 or γ. We rely on simulation to estimate the shape of this contribution.

Figure 5.1 shows the fit of the sum of three bifurcated gaussians to the invariant mass distribution of simulated $B_s^0 \to {D_s}^* \pi\pi\pi$ event. The pion or photon from ${D_s}^* \to D_s(\gamma/\pi^0)$ is excluded from the reconstruction. The obtained shape parameters are used as input values for the nominal $m(D_s\pi\pi\pi)$ mass fit. The yield of this contribution is directly determined in the nominal fit.

5.3 Background models for $m(D_sK\pi\pi)$

For the signal channel, the following background sources have to be considered:

- combinatorial background: Same contributions as discussed in Sec. 5.2.
- Partially reconstructed $B_s^0 \to {D_s}^* K\pi\pi$ decays, with ${D_s}^* \to D_s\gamma$ or ${D_s}^* \to D_s\pi^0$, where the γ/π^0 is not reconstructed in the decay chain.
- Partially reconstructed $B^0 \to {D_s}^* K\pi\pi$ decays, with ${D_s}^* \to D_s\gamma$ or ${D_s}^* \to D_s\pi^0$, where the γ/π^0 is not reconstructed in the decay chain.
- miss-identified $B_s^0 \to D_s\pi\pi\pi$ decays, where one of the pions is wrongly identified as a kaon $\pi \to K$.

- miss-identified, partially reconstructed $B_s^0 \to D_s{}^*\pi\pi\pi$ decays, where one of the pions is wrongly identified as a kaon $\pi \to K$ and the γ/π^0 from $D_s{}^* \to D_s\gamma/\pi^0$ is not reconstructed.

Again the combinatorial background is expected to be flat in the spectrum of the invariant mass of $B_s^0 \to D_s K\pi\pi$ candidates. An exponential function is used to model this contribution.
The shape of the partially reconstructed $B_s^0/B^0 \to D_s{}^*K\pi\pi$ background is taken from simulation. {I think we take them from the normalization mode} A MC sample of $B_s^0 \to D_s{}^*K\pi\pi$ events, where the γ/π^0 is excluded from the reconstruction, is generated. The sum of three bifurcated gaussians is then fitted to the mass distribution of B_s^0 candidates. The distribution and the overlaid fit is shown in Fig. 5.2.

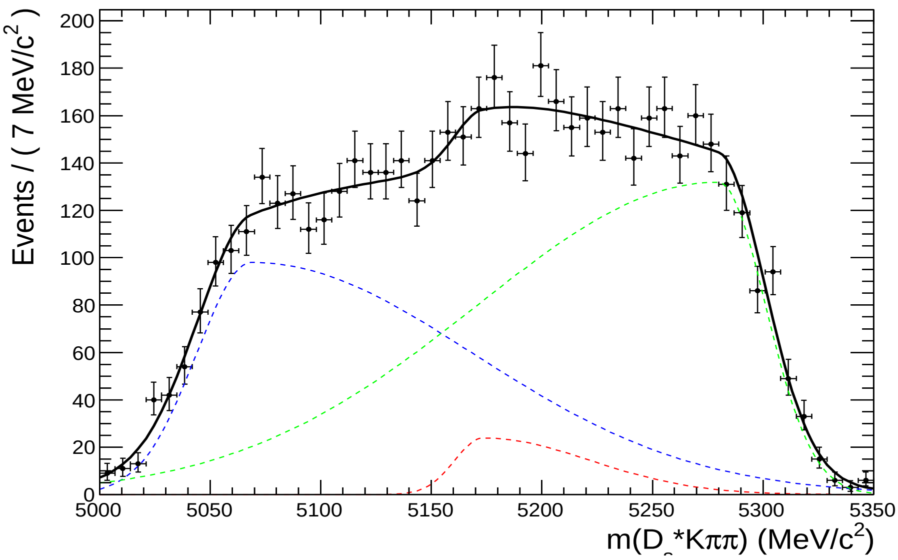

Figure 5.2: Invariant mass distribution of simulated $B_s^0 \to D_s{}^*K\pi\pi$ events, where the γ/π^0 is excluded from the reconstruction. A fit of the sum of three bifurcated gaussians to this distribution is overlaid.

The obtained shape parameters are used as input values for the nominal $m(D_sK\pi\pi)$ mass fit. For the contribution of the $B^0 \to D_s{}^*K\pi\pi$ background, the same shape is used, but the means μ_i of the bifurcated gaussians are shifted down by $m_{B_s^0} - m_{B^0}$ [4]. The yield of both contributions are directly determined in the nominal fit.
To determine the shape of miss-identified $B_s^0 \to D_s\pi\pi\pi$ candidates in the $m(D_sK\pi\pi)$ spectrum, we take a truth matched signal MC sample of our normalization channel. We then use the PIDCalib package to determine the $\pi \to K$ fake rate. For every candidate in our MC sample, a p and η-dependent event weight is computed and assigned. We flip the particle hypothesis from pion to kaon for the π with the biggest miss-ID weight for each

event and recompute the invariant B_s^0 mass. This distribution is then modelled using two crystal ball functions. The distribution and fit is shown in Fig. 5.3(left).

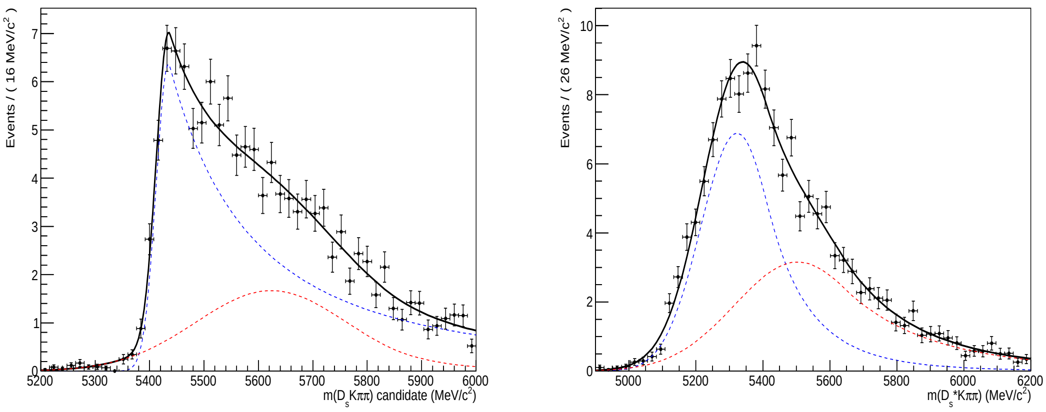

Figure 5.3: Invariant mass distribution of (left) simulated $B_s^0 \to D_s\pi\pi\pi$ events, where one of the π's is reconstructed as a K and the miss-ID probability for each event is taken into account. The corresponding distribution for simulated $B_s^0 \to {D_s}^*\pi\pi\pi$ events, where the γ/π^0 from the ${D_s}^*$ is excluded from reconstruction, is shown on the right. A fit of the sum of two crystal ball functions to each of these distributions is overlaid.

The expected yield of miss-identified $B_s^0 \to D_s\pi\pi\pi$ candidates in the $m(D_sK\pi\pi)$ spectrum is computed by multiplying the fake probability of $\propto$ 3.2%, which is derived from PIDCalib, by the yield of $B_s^0 \to D_s\pi\pi\pi$ signal candidates, determined in the nominal mass fit of our normalization channel.
In the same way as mentioned above, we can determine the rate of miss-identified, partially reconstructed $B_s^0 \to {D_s}^*\pi\pi\pi$ decays in our sample of $B_s^0 \to D_sK\pi\pi$ decays using PIDCalib and a MC sample of $B_s^0 \to {D_s}^*\pi\pi\pi$ events. The invariant mass distribution we obtain when we exlude the γ/π^0, flip the the particle hypothesis $\pi \to K$ and apply the event weights given by the fake rate, is shown in Fig. 5.3 (right). The fit of two crystal ball functions to this distribution is overlaid. The yield of this contribution is determined from the yield of $B_s^0 \to {D_s}^*\pi\pi\pi$ candidates in the nominal mass fit of our normalization channel, multiplied by the miss-ID probability of $\propto$ 3.6%.

6 Massfits for signal and normalization channel

This section describes the nominal fits to the invariant mass distribution of $B_s^0 \to D_sK\pi\pi$ and $B_s^0 \to D_s\pi\pi\pi$ candidates after all selection steps, described in the previous Sections, are applied. The obtained yields are summarized in Tab. 6.1.

6.1 Fit to $B_s^0 \to D_s\pi\pi\pi$ candidates

An unbinned maximum likelihood fit is performed to the invariant mass distribution of $B_s^0 \to D_s\pi\pi\pi$ candidates. As discussed in Sec. 5.1, the fit is given as the sum of the double gaussian signal model, the sum of three bifurcated gaussians to model the partially reconstructed $B_s^0 \to D_s{}^*\pi\pi\pi$ background, as well as an exponential to account for combinatorial background. The invariant mass distribution and the fit to it is shown in Fig. 6.1.

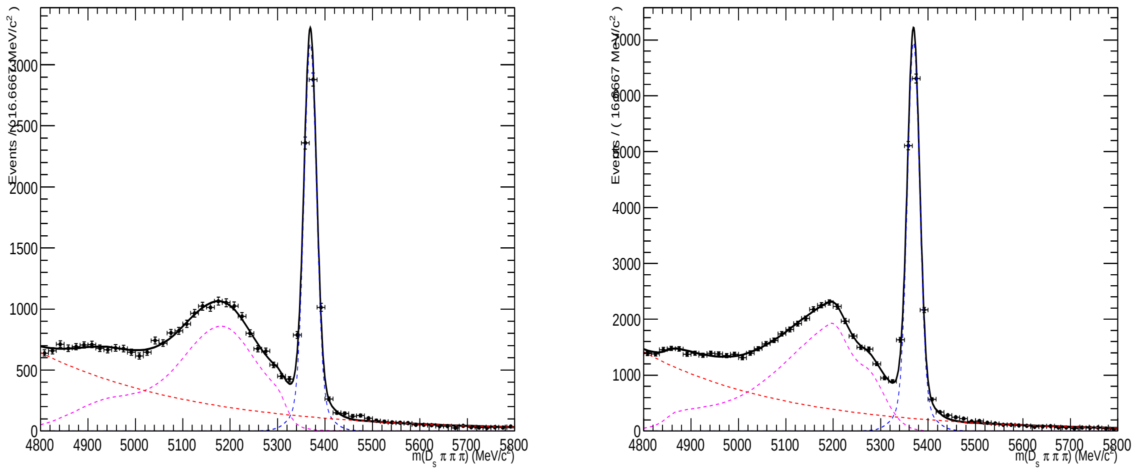

Figure 6.1: Invariant mass distribution of $B_s^0 \to D_s\pi\pi\pi$ candidates for (left) 2011 and (right) 2012 data. A fit described in the text is overlaid. The dashed lines show the (green) partially reconstructed and (red) combinatorial background, as well as the (blue) signal component.

The determined number of $B_s^0 \to D_sK\pi\pi$ decays is 7173 ± 115 for 2011 data and 15640 ± 151 for 2012 data. The determined yield for the partially reconstructed $B_s^0 \to D_s{}^*\pi\pi\pi$ background is (2011) 13685 ± 449 and (2012) $28702e+04 \pm 573$, while the yield for the combinatorial background is (2011) 12193 ± 457 and (2012) 25212 ± 564.

6.2 Fit to $B_s^0 \to D_sK\pi\pi$ candidates

Fig. 6.2 shows the invariant mass distribution of $B_s^0 \to D_sK\pi\pi$ candidates. A unbinned maximum likelihood fit is overlaid, which consists of two double gaussian models for the B^0 and B_s^0 signal, two sums of three bifurcated gaussians for the $B_s^0/B^0 \to D_s{}^*K\pi\pi$ partially reconstructed background contributions and two sums of double crystal ball functions for the single miss-ID $B_s^0 \to D_s\pi\pi\pi$ and the partially reconstructed, miss-identified $B_s^0 \to D_s{}^*\pi\pi\pi$ decays.
The extracted signal yields are (2011) 332 ± 27 and (2012) 787 ± 39.

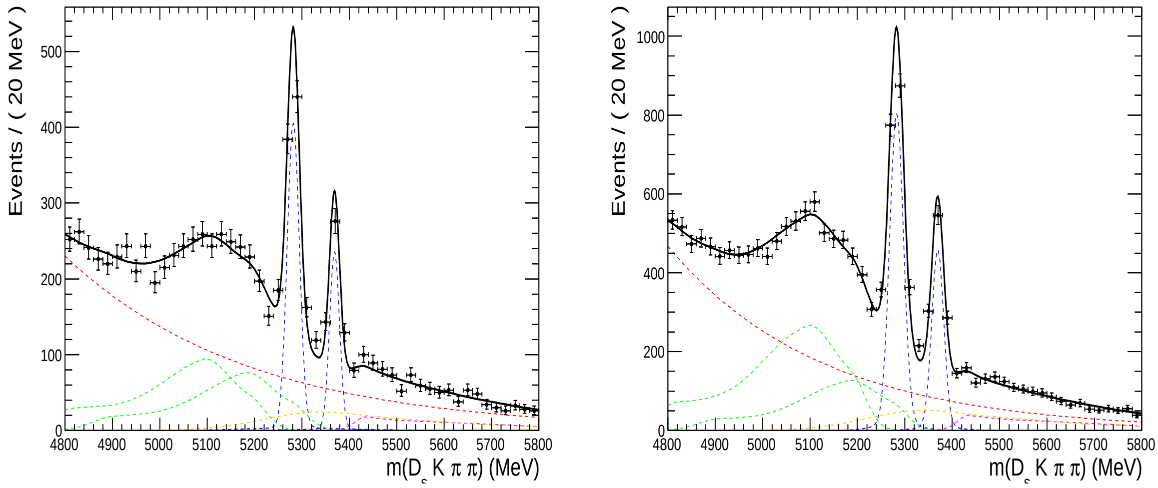

Figure 6.2: Invariant mass distribution of $B_s^0 \to D_s K\pi\pi$ candidates for (left) 2011 and (right) 2012 data. A fit described in the text is overlaid. The dashed lines show the (green) partially reconstructed and (red) combinatorial background, as well as the (blue) signal component. Additional, the dashed magenta line depicts the miss-ID background and the dashed yellow line shows the miss-identified, partially reconstructed background component.

Decay	yield 2011	yield 2012
$B_s^0 \to D_s K\pi\pi$	332 ± 27	787 ± 39
$B_s^0 \to D_s \pi\pi\pi$	7173 ± 115	15640 ± 151

Table 6.1: Summary of signal yields from the fits to 2011 and 2012 data.

7 Efficiency corrections

Several relative efficiency corrections are needed to measure the branching fraction of $B_s^0 \to D_s K\pi\pi$ with respect to $B_s^0 \to D_s \pi\pi\pi$. Precise knowledge of the efficiency related to the detector acceptance, PID requirements, used trigger lines and offline selections are crucial for both, the determination of γ and the branching ratio measurement.

7.1 Relative efficiency for BR measurement

For the branching ratio measurement, the relative efficiency is given by

$$\epsilon_{rel} = \epsilon_{rel}^{acc} \cdot \epsilon_{rel}^{sel} \cdot \epsilon_{rel}^{pid}, \tag{7.1}$$

where $\epsilon = \frac{\epsilon_{Norm}}{\epsilon_{Sig}}$ is the ratio of the efficiency for the signal and normalization mode. To evaluate these efficiencies, we rely on simulation. The three efficiencies given in Eq. 7.1 are:

- ϵ_{rel}^{acc}: This is the relative efficiency due to the geometrical acceptance of the LHCb detector. All tracks are required to have a polar angle between 10 and 400 mrad and a minimal momentum of $|p| > 1.6$ GeV/c in order to be recorded for further analysis. Since the particle species of one track differs between the signal and normalization mode, the efficiencies caused by the geometrical acceptance are expected to be different for the two channels.

- ϵ_{rel}^{sel}: The relative selection efficiency due to trigger and offline requirements.

- ϵ_{rel}^{pid}: The relative PID efficiency due to the identification likelihood requirements for tracks from both modes. This is evaluated using efficiencies from $D^{*+} \to D^0(K^-\pi^+)\pi^+$ calibration data, which is weighted by the expected momentum (p) distribution taken from simulation.

Using the definition given in Eq. 7.1, the branching ratio can be expressed as

$$\frac{\mathcal{B}(B_s^0 \to D_s K\pi\pi)}{\mathcal{B}(B_s^0 \to D_s\pi\pi\pi)} = \frac{\mathcal{Y}(B_s^0 \to D_s K\pi\pi)}{\mathcal{Y}(B_s^0 \to D_s\pi\pi\pi)}, \cdot\epsilon_{rel} \tag{7.2}$$

where $\mathcal{Y}(x)$ represents the yield of the respective channel.
The single efficiencies, as well as the total selection efficiency, for the signal and normalization channel, is given in Table 7.1.

Efficiency (%)	$B_s^0 \to D_s K\pi\pi$	$B_s^0 \to D_s\pi\pi\pi$
2011 ϵ^{acc}	15.84 $\pm$ 0.04	9.85 $\pm$ 0.04
2012 ϵ^{acc}	16.11 $\pm$ 0.04	yyy
2011 ϵ^{sel}	0.658 $\pm$ 0.011	0.894 $\pm$ 0.013
2012 ϵ^{sel}	0.574 $\pm$ 0.008	yyy
2011 ϵ^{pid}	74.88 $\pm$ 0.85	92.64 $\pm$ 0.47
2012 ϵ^{pid}	74.30 $\pm$ 0.85	-
2011 total ϵ	0.078 $\pm$ 0.002	0.082 $\pm$ 0.001
2012 total ϵ	0.069 $\pm$ 0.002	zz

Table 7.1: Efficiencies due to the detector acceptance, selection requirements and PID cuts for the signal and normalization mode. All values are obtained using simulated events.

8 Systematic errors

Several systematic errors contribute to the overall uncertainty on the brachning fractions. We consider the most significant ones:

- Particle identification

- Signal and background models

- Determination of the selection efficiency with MC
- MC statistics
- BDTG efficiency

Text with short description of every source and how we determine systematic uncertainty.

Source	Uncertainty on $\frac{\mathcal{B}(B_s^0\to D_s K\pi\pi)}{\mathcal{B}(B_s^0\to D_s\pi\pi\pi)}$ [%]
PID	
Fit model

Table 8.1: Summary of considered systematic uncertainties on the branching ratio determination.

9 Results and summary

Using the definition of the branching ratio given in Eq. 7.2, we compute from the measured yields and efficiencies:

$$\frac{\mathcal{B}(B_s^0 \to D_s K\pi\pi)}{\mathcal{B}(B_s^0 \to D_s\pi\pi\pi)} = 0.051 \pm 0.002 \pm 0.xxx, \tag{9.1}$$

where the uncertainties are statistical and systematical, respectively. Further discussion...
