Abstract

We present the first measurement of the weak phase $\gamma - 2\beta_s$ obtained from a time-dependent (amplitude) analysis of $B_s^0 \rightarrow D_s K \pi\pi$ decays using proton-proton collision data corresponding to an integrated luminosity of 7 fb^{-1} recorded by the LHCb detector.

Change-log

- Version 1.0: First note draft circulated to the WG
- Version 2.0: Implemented first round of comments from Mark, Alessandro, Agnieszka
 - Minor text changes throughout the note
 - Changed D^0 bkg vetoes (Sec. 3.2.2)
 - Revisited some systematics
 - * Use uncertainty from fake rate instead of fixing misID yield to 0 or twice the value (Sec. 11.2)
 - * Use GLASS model instead of RBW as alternative to LASS model for $K\pi$ S-wave (Sec. 11.9)
 - * Instead of assuming pure phase space, recalculate running width of three-body resonances taking only the dominant $K\pi\pi$ decay mode into account (Sec. 11.9)
 - * Calculate RMS of lineshape variations instead of summing them up in quadrature (Sec. 11.9)
 - * Bug fix in evaluation of fixed lineshape parameters (mass, width, form-factor) systematic (Sec. 11.9)
 - Added tables with alternative amplitude models (Sec. 11.10)
 - Added comparison plots of 16 vs 17 data (Sec. K)
- Version 3.0:
 - Changed D^0 bkg vetoes back to the ones from v1.0 to account for additional Kaon misID (Fig. 3.3)
 - Updated analysis with new MC samples (Sec. 3.3)
 - Studied time resolution separately for 16 and 17 data (Sec. 5.2)
 - Changed phasespace acceptance method from BDT to MC integration (Sec. 6.3)
 - Updated analysis with latest OS Tagger tuning (Sec. 7.1)
- Version 3.1: Minor changes, approved by Mark and Alessandro

1 Introduction

This note presents the first measurement of the CKM angle $\gamma \equiv \arg[-(V_{ud}V_{ub}^*)/(V_{cd}V_{cb}^*)]$ using $B_s^0 \rightarrow D_s K\pi\pi$ decays, where the $K\pi\pi$ subsystem is dominated by excited kaon states such as the $K_1(1270)$ and $K_1(1400)$ resonances [1, 2]. In these decays, sensitivity to the weak phase results from the interference between $b \rightarrow c$ and $b \rightarrow u$ transitions achieved through $B_s^0 - \bar{B}_s^0$ mixing [3, 4]. The amplitudes for both processes are of the same order in the Wolfenstein parameters λ , $\mathcal{O}(\lambda^3)$, so that interference effects are expected to be large. The corresponding Feynman diagrams are shown in Fig. 1.1. Due to the interference between mixing and decay amplitudes, the physical CP violating observables in these decays are functions of a combination of γ and the mixing phase β_s , namely $\gamma - 2\beta_s$. To account for the non-constant strong phase across the phase space, one can either perform a time-dependent amplitude fit or select a suitable phase-space region and introduce a coherence factor as additional hadronic parameter to the decay-time fit. The topologically very similar yet flavour specific decay $B_s \rightarrow D_s \pi\pi\pi$ is used as calibration channel, not only to calibrate the tagging algorithms and determine the decay-time acceptance but also to constrain the $B_s^0 - \bar{B}_s^0$ mixing frequency. The branching ration of these decay modes was measured by LHCb to be $\frac{\mathcal{B}(B_s^0 \rightarrow D_s K\pi\pi)}{\mathcal{B}(B_s^0 \rightarrow D_s \pi\pi\pi)} = 0.052 \pm 0.005(\text{stat}) \pm 0.003(\text{syst})$ [1, 2].

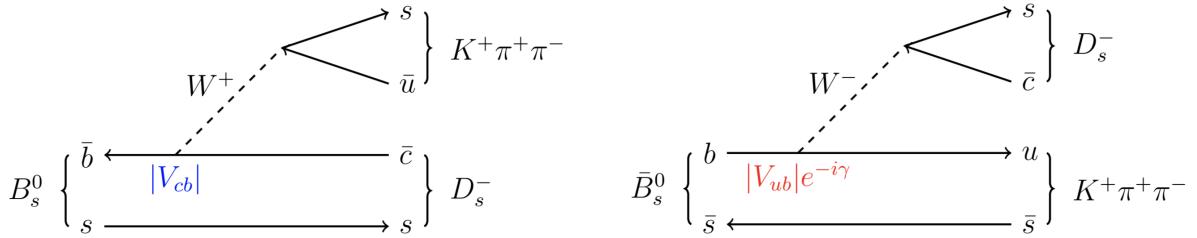

Figure 1.1: Feynman diagram for $B_s^0/\bar{B}_s^0 \rightarrow D_s^- K^+ \pi^+ \pi^-$ decays.

18 2 Formalism

19 2.1 Decay rates and *CP*-observables

20 The differential decay rate of B_s^0 or \bar{B}_s^0 decays to the final state $D_s^- K^+ \pi\pi$ or $D_s^+ K^- \pi\pi$ is
 21 given by:

$$\frac{d\Gamma(\mathbf{x}, t, q, f)}{e^{-\Gamma_s t} dt d\Phi_4} \propto (|\mathcal{A}_f^c(\mathbf{x})|^2 + |\mathcal{A}_f^u(\mathbf{x})|^2) \cosh\left(\frac{\Delta\Gamma_s t}{2}\right) \\ + q f (|\mathcal{A}_f^c(\mathbf{x})|^2 - |\mathcal{A}_f^u(\mathbf{x})|^2) \cos(\Delta m_s t) \\ - 2\text{Re}(\mathcal{A}_f^c(\mathbf{x})^* \mathcal{A}_f^u(\mathbf{x}) e^{-if(\gamma-2\beta_s)}) \sinh\left(\frac{\Delta\Gamma_s t}{2}\right) \\ - 2q f \text{Im}(\mathcal{A}_f^c(\mathbf{x})^* \mathcal{A}_f^u(\mathbf{x}) e^{-if(\gamma-2\beta_s)}) \sin(\Delta m_s t) \quad (2.1)$$

22 where $q = +1$ (-1) refers to an initially produced B_s^0 (\bar{B}_s^0) flavour eigenstate, $q = 0$ to an
 23 undetermined initial flavour, $f = +1$ or -1 denotes $D_s^- K^+ \pi\pi$ or $D_s^+ K^- \pi\pi$ final states and
 24 Γ_s , $\Delta\Gamma_s$ and Δm_s are the width average, the width difference and the mass difference of
 25 the two B_s mass eigenstates. We choose a convention in which $\Delta\Gamma_s < 0$ and $\Delta m_s > 0$.
 26 We further assume $|q/p| = 1$ for the complex coefficients p and q which relate the B_s
 27 meson mass eigenstates to the flavour eigenstates (no *CP* violation in the mixing). The
 28 CKM angle γ can be extracted from the *CP* violating phase associated to the interference
 29 between mixing and decay, $\gamma - 2\beta_s$, since the $B_s^0 - \bar{B}_s^0$ mixing phase, β_s , is well constrained
 30 from $B_s \rightarrow J/\psi \phi$ and related modes.

31 The static total decay amplitudes $\mathcal{A}_f^c(\mathbf{x})$ and $\mathcal{A}_f^u(\mathbf{x})$ are given by the coherent sum
 32 over all intermediate state amplitudes $A_i(\mathbf{x})$, each weighted by a complex coefficient to be
 33 determined from data,

$$\mathcal{A}(B_s^0 \rightarrow D_s^- K^+ \pi\pi) \equiv \mathcal{A}_f^c(\mathbf{x}) = \sum_i a_i^c A_i(\mathbf{x}) \quad (2.2)$$

$$\mathcal{A}(\bar{B}_s^0 \rightarrow D_s^- K^+ \pi\pi) \equiv \mathcal{A}_f^u(\mathbf{x}) = \sum_i a_i^u A_i(\mathbf{x}) \quad (2.3)$$

34 where the superscript c (u) indicates a $b \rightarrow c$ ($b \rightarrow u$) quark-level transition and \mathbf{x}
 35 represents a unique set of kinematic conditions within the five-dimensional phase space
 36 of the decay. Convenient choices for the kinematic observables include the invariant
 37 mass combinations of the final state particles or acoplanarity and helicity angles. In
 38 practice, we do not need to choose a particular five-dimensional basis, but use the full
 39 four-vectors of the decay in our analysis. The dimensionality is handled by the phase
 40 space element which can be written in terms of any set of five independent kinematic
 41 observables, $\mathbf{x} = (x_1, \dots, x_5)$, as

$$d\Phi_4 = \phi_4(\mathbf{x}) d^5 x, \quad (2.4)$$

42 where $\phi_4(\mathbf{x}) = \left| \frac{\partial\Phi_4}{\partial(x_1, \dots, x_5)} \right|$ is the phase space density. In contrast to three-body decays,
 43 the four-body phase space density function is not flat in the usual kinematic variables.
 44 Therefore, an analytic expression for ϕ_4 is taken from Ref. [5].

⁴⁵ Assuming there is no direct CP violation in the B_s decay implies for the CP conjugate
⁴⁶ transition amplitudes:

$$\mathcal{A}(\bar{B}_s^0 \rightarrow \bar{f}) = \mathcal{A}_f^c(\mathbf{x}) = \mathcal{A}_f^c(\bar{\mathbf{x}}) \quad (2.5)$$

$$\mathcal{A}(B_s^0 \rightarrow \bar{f}) = \mathcal{A}_f^u(\mathbf{x}) = \mathcal{A}_f^u(\bar{\mathbf{x}}) \quad (2.6)$$

⁴⁷ where the CP -conjugate phase space point $\bar{\mathbf{x}}$ is defined such that it is mapped onto \mathbf{x} by
⁴⁸ the interchange of final state charges, and the reversal of three-momenta.

⁴⁹ The phenomenological description of the intermediate state amplitudes is discussed
⁵⁰ in Sec. 2.2. For a model-independent measurement, the differential decay rate can be
⁵¹ integrated over the phase space:

$$\int \frac{d\Gamma(x, t, q, f)}{e^{-\Gamma_s t} dt d\Phi_4} d\Phi_4 \propto \cosh\left(\frac{\Delta\Gamma_s t}{2}\right) + q f C \cos(\Delta m_s t) \\ + D_f \sinh\left(\frac{\Delta\Gamma_s t}{2}\right) - q S_f \sin(\Delta m_s t) \quad (2.7)$$

⁵² where the same convention for the CP coefficients as for the $B_s \rightarrow D_s K$ analysis is used:

$$C = \frac{1 - r^2}{1 + r^2} \quad (2.8)$$

$$D_f = -\frac{2 r \kappa \cos(\delta - q_f (\gamma - 2\beta_s))}{1 + r^2} \quad (2.9)$$

$$S_f = f \frac{2 r \kappa \sin(\delta - q_f (\gamma - 2\beta_s))}{1 + r^2} \quad (2.10)$$

⁵³ The coherence factor κ , the strong phase difference δ and the ratio of the suppressed
⁵⁴ ($b \rightarrow u$) over favored ($b \rightarrow c$) decay mode, averaged over the phase space, are defined as:

$$\kappa e^{i\delta} \equiv \frac{\int \mathcal{A}_f^c(x)^* \mathcal{A}_f^u(x) d\Phi_4}{\sqrt{\int |\mathcal{A}_f^c(x)|^2 d\Phi_4} \sqrt{\int |\mathcal{A}_f^u(x)|^2 d\Phi_4}} \quad (2.11)$$

$$r \equiv \frac{\sqrt{\int |\mathcal{A}_f^u(x)|^2 d\Phi_4}}{\sqrt{\int |\mathcal{A}_f^c(x)|^2 d\Phi_4}}. \quad (2.12)$$

⁵⁵ The coherence factor dilutes the sensitivity to the weak phase γ due to the integration
⁵⁶ over the interfering amplitudes across the phase space. The value of κ is bounded between
⁵⁷ zero and unity. The latter corresponds to the limit of only one contributing intermediate
⁵⁸ state in which case the same sensitivity as in $B_s \rightarrow D_s K$ decays is reached, while $\kappa = 0$
⁵⁹ would result in no sensitivity to γ at all.

60 2.2 Amplitude model

61 To construct the intermediate state amplitudes $A_i(\mathbf{x})$, the isobar approach is used, which
 62 assumes that the decay process can be factorized into subsequent two-body decay am-
 63 plitudes [6–8]. This gives rise to two different decay topologies; quasi two-body decays
 64 $B_s \rightarrow (R_1 \rightarrow h_1 h_2) (R_2 \rightarrow h_3 h_4)$ or cascade decays $B_s \rightarrow h_1 [R_1 \rightarrow h_2 (R_2 \rightarrow h_3 h_4)]$. In
 65 either case, the intermediate state amplitude is parameterized as a product of orbital
 66 angular momentum, L , dependent form factors B_L , included for each vertex of the decay
 67 tree, Breit-Wigner propagators T_R , included for each resonance R , and an overall angular
 68 distribution represented by a spin factor S ,

$$A_i(\mathbf{x}) = B_{L_{B_s}}(\mathbf{x}) [B_{L_{R_1}}(\mathbf{x}) T_{R_1}(\mathbf{x})] [B_{L_{R_2}}(\mathbf{x}) T_{R_2}(\mathbf{x})] S_i(\mathbf{x}). \quad (2.13)$$

69 The following description of the individual components is adapted from Ref. [9] and
 70 only included for completeness.

71 2.2.1 Form Factors and Resonance Lineshapes

72 To account for the finite size of the decaying resonances, the Blatt-Weisskopf penetration
 73 factors, derived in Ref. [10] by assuming a square well interaction potential with radius
 74 r_{BW} , are used as form factors, B_L . They depend on the breakup momentum q , which is
 75 defined as the magnitude of the three-momentum of one of the daughters in the rest frame
 76 of the decaying resonance and the orbital angular momentum L , between the resonance
 77 daughters. Their explicit expressions are

$$\begin{aligned} B_0(q) &= 1, \\ B_1(q) &= 1/\sqrt{1 + (q r_{\text{BW}})^2}, \\ B_2(q) &= 1/\sqrt{9 + 3 (q r_{\text{BW}})^2 + (q r_{\text{BW}})^4}. \end{aligned} \quad (2.14)$$

78 Resonance lineshapes are described as function of the energy-squared, s , by Breit-Wigner
 79 propagators

$$T(s) = \frac{1}{m_0^2 - s - i m_0 \Gamma(s)}, \quad (2.15)$$

80 where the total width, $\Gamma(s)$, is normalized to give the nominal width, Γ_0 , when evaluated
 81 at the nominal mass m_0 .

82 For a decay into two stable particles $R \rightarrow AB$, the energy dependence of the decay
 83 width can be described by

$$\Gamma_{R \rightarrow AB}^{(2)}(s) = \Gamma_0 \frac{m_0}{\sqrt{s}} \left(\frac{q}{q_0} \right)^{2L+1} \frac{B_L(q)^2}{B_L(q_0)^2}, \quad (2.16)$$

84 where q_0 is the value of the breakup momentum at the resonance pole [11].

85 The energy-dependent width for a three-body decay $R \rightarrow ABC$, on the other hand, is
 86 considerably more complicated and has no analytic expression in general. However, it can
 87 be obtained numerically by integrating the transition amplitude-squared over the phase
 88 space,

$$\Gamma_{R \rightarrow ABC}^{(3)}(s) = \frac{1}{2\sqrt{s}} \int |A_{R \rightarrow ABC}|^2 d\Phi_3, \quad (2.17)$$

and therefore requires knowledge of the resonant substructure. The three-body amplitude $A_{R \rightarrow ABC}$ can be parameterized similarly to the four-body amplitude in Eq. (2.13). In particular, it includes form factors and propagators of intermediate two-body resonances.

Both Eq. (2.16) and Eq. (2.17) give only the partial width for the decay into a specific channel. To obtain the total width, a sum over all possible decay channels has to be performed,

$$\Gamma(s) = \sum_i g_i \Gamma_i(s), \quad (2.18)$$

where the coupling strength to channel i , is given by g_i .

The treatment of the lineshape for various resonances considered in this analysis is described in what follows. The nominal masses and widths of the resonances are taken from the PDG [12] with the exceptions described below.

For the broad scalar resonance σ , the model from Bugg is used [13]. We use the Gounaris-Sakurai parametrization for the $\rho(770)^0 \rightarrow \pi\pi$ propagator [14]. For the decay chain $K_1(1270) \rightarrow \rho(770)K$, we include $\rho-\omega$ mixing with the relative magnitude and phase between ρ and ω fixed to the values determined in Ref. [15]. The energy-dependent width of the $f_0(980)$ resonance is given by the sum of the partial widths into the $\pi\pi$ and KK channels (*i.e.* the Flatté lineshape [16]), where the coupling constants as well as the mass and width are taken from a measurement performed by the BES Collaboration [17]. For the $f_2(1270)$ and the $f_0(1370)$ mesons we use the total decay widths calculated in Ref. [9] which take the channels $\pi\pi$, KK , $\eta\eta$ and $\pi\pi\pi\pi$ into account. The Lass parameterization is used to model the $K\pi$ S -wave contribution. It consists of the $K_0^*(1430)$ resonance together with an effective range non-resonant component [18–20]:

$$T_{Lass}(s) = \frac{\sqrt{s}}{q \cot \delta_L - iq} + e^{2i\delta_L} \frac{m_0 \Gamma_0 \frac{m_0}{q_0}}{m_0^2 - s - i m_0 \Gamma_0 \frac{m_0}{\sqrt{s}} \frac{q}{q_0}} \quad (2.19)$$

with $\cot \delta_L = \frac{1}{aq} + \frac{1}{2}rq$. We use the values for the scattering length a and effective range parameter r from Ref. [18, 19]. Equation (2.16) is used for all other resonances decaying into a two-body final state.

For the resonances $K_1(1270)$ and $K(1460)$, the energy-dependent widths as well as the nominal mass and width are taken from Ref. [21]. We further use the energy-dependent widths for the $K_1(1400)$, $K^*(1410)$ and $K^*(1680)$ mesons from Ref. [9]. For all other resonances decaying into a three-body final state, an energy-dependent width distribution is derived from Equation 2.17 assuming an uniform phase space population.

Some particles may not originate from a resonance but are in a state of relative orbital angular momentum. We denote such non-resonant states by surrounding the particle system with brackets and indicate the partial wave state with an subscript; for example $(\pi\pi)_S$ refers to a non-resonant di-pion S -wave. The lineshape for non-resonant states is set to unity.

124 2.2.2 Spin Densities

125 The spin amplitudes are phenomenological descriptions of decay processes that are required
 126 to be Lorentz invariant, compatible with angular momentum conservation and, where
 127 appropriate, parity conservation. They are constructed in the covariant Zemach (Rarita-
 128 Schwinger) tensor formalism [22–24]. At this point, we briefly introduce the fundamental
 129 objects of the covariant tensor formalism which connect the particle’s four-momenta to
 130 the spin dynamics of the reaction and give a general recipe to calculate the spin factors
 131 for arbitrary decay trees. Further details can be found in Refs. [25, 26].

132 A spin- S particle with four-momentum p , and spin projection λ , is represented by the
 133 polarization tensor $\epsilon_{(S)}(p, \lambda)$, which is symmetric, traceless and orthogonal to p . These
 134 so-called Rarita-Schwinger conditions reduce the a priori 4^S elements of the rank- S tensor
 135 to $2S + 1$ independent elements in accordance with the number of degrees of freedom of a
 136 spin- S state [23, 27].

137 The spin projection operator $P_{(S)}^{\mu_1 \dots \mu_S \nu_1 \dots \nu_S}(p_R)$, for a resonance R , with spin $S =$
 138 $\{0, 1, 2\}$, and four-momentum p_R , is given by [26]:

$$\begin{aligned} P_{(0)}^{\mu\nu}(p_R) &= 1 \\ P_{(1)}^{\mu\nu}(p_R) &= -g^{\mu\nu} + \frac{p_R^\mu p_R^\nu}{p_R^2} \\ P_{(2)}^{\mu\nu\alpha\beta}(p_R) &= \frac{1}{2} \left[P_{(1)}^{\mu\alpha}(p_R) P_{(1)}^{\nu\beta}(p_R) + P_{(1)}^{\mu\beta}(p_R) P_{(1)}^{\nu\alpha}(p_R) \right] - \frac{1}{3} P_{(1)}^{\mu\nu}(p_R) P_{(1)}^{\alpha\beta}(p_R), \end{aligned} \quad (2.20)$$

139 where $g^{\mu\nu}$ is the Minkowski metric. Contracted with an arbitrary tensor, the projection
 140 operator selects the part of the tensor which satisfies the Rarita-Schwinger conditions.

141 For a decay process $R \rightarrow AB$, with relative orbital angular momentum L , between
 142 particle A and B , the angular momentum tensor is obtained by projecting the rank- L
 143 tensor $q_R^{\nu_1} q_R^{\nu_2} \dots q_R^{\nu_L}$, constructed from the relative momenta $q_R = p_A - p_B$, onto the spin- L
 144 subspace,

$$L_{(L)\mu_1 \dots \mu_L}(p_R, q_R) = (-1)^L P_{(L)\mu_1 \dots \mu_L \nu_1 \dots \nu_L}(p_R) q_R^{\nu_1} \dots q_R^{\nu_L}. \quad (2.21)$$

145 Their $|\vec{q}_R|^L$ dependence accounts for the influence of the centrifugal barrier on the transition
 146 amplitudes. For the sake of brevity, the following notation is introduced,

$$\begin{aligned} \varepsilon_{(S)}(R) &\equiv \varepsilon_{(S)}(p_R, \lambda_R), \\ P_{(S)}(R) &\equiv P_{(S)}(p_R), \\ L_{(L)}(R) &\equiv L_{(L)}(p_R, q_R). \end{aligned} \quad (2.22)$$

147 Following the isobar approach, a four-body decay amplitude is described as a product
 148 of two-body decay amplitudes. Each sequential two-body decay $R \rightarrow A B$, with relative
 149 orbital angular momentum L_{AB} , and total intrinsic spin S_{AB} , contributes a term to the
 150 overall spin factor given by

$$\begin{aligned} S_{R \rightarrow AB}(\mathbf{x}|L_{AB}, S_{AB}; \lambda_R, \lambda_A, \lambda_B) &= \varepsilon_{(S_R)}(R) X(S_R, L_{AB}, S_{AB}) L_{(L_{AB})}(R) \\ &\times \Phi(\mathbf{x}|S_{AB}; \lambda_A, \lambda_B), \end{aligned} \quad (2.23)$$

151 where

$$\Phi(\mathbf{x}|S_{AB}; \lambda_A, \lambda_B) = P_{(S_{AB})}(R) X(S_{AB}, S_A, S_B) \varepsilon_{(S_A)}^*(A) \varepsilon_{(S_B)}^*(B). \quad (2.24)$$

152 Here, a polarization vector is assigned to the decaying particle and the complex conjugate
 153 vectors for each decay product. The spin and orbital angular momentum couplings are
 154 described by the tensors $P_{(S_{AB})}(R)$ and $L_{(L_{AB})}(R)$, respectively. Firstly, the two spins S_A
 155 and S_B , are coupled to a total spin- S_{AB} state, $\Phi(\mathbf{x}|S_{AB})$, by projecting the corresponding
 156 polarization vectors onto the spin- S_{AB} subspace transverse to the momentum of the
 157 decaying particle. Afterwards, the spin and orbital angular momentum tensors are
 158 properly contracted with the polarization vector of the decaying particle to give a Lorentz
 159 scalar. This requires in some cases to include the tensor $\varepsilon_{\alpha\beta\gamma\delta} p_R^\delta$ via

$$X(j_a, j_b, j_c) = \begin{cases} 1 & \text{if } j_a + j_b + j_c \text{ even} \\ \varepsilon_{\alpha\beta\gamma\delta} p_R^\delta & \text{if } j_a + j_b + j_c \text{ odd} \end{cases}, \quad (2.25)$$

160 where $\varepsilon_{\alpha\beta\gamma\delta}$ is the Levi-Civita symbol and j refers to the arguments of X defined in
 161 Eqs. 2.23 and 2.24. Its antisymmetric nature ensures the correct parity transformation
 162 behavior of the amplitude. The spin factor for a whole decay chain, for example $R \rightarrow$
 163 $(R_1 \rightarrow AB)(R_2 \rightarrow CD)$, is obtained by combining the two-body terms and performing a
 164 sum over all unobservable, intermediary spin projections

$$\sum_{\lambda_{R_1}, \lambda_{R_2}} S_{R \rightarrow R_1 R_2}(\mathbf{x}|L_{R_1 R_2}; \lambda_{R_1}, \lambda_{R_2}) S_{R_1 \rightarrow AB}(\mathbf{x}|L_{AB}; \lambda_{R_1}) S_{R_2 \rightarrow CD}(\mathbf{x}|L_{CD}; \lambda_{R_2}), \quad (2.26)$$

165 where $\lambda_R = \lambda_A = \lambda_B = \lambda_C = \lambda_D = 0$, $S_{AB} = S_{CD} = 0$ and $S_{R_1 R_2} = L_{R_1 R_2}$, as only
 166 pseudoscalar initial/final states are involved.

167 The spin factors for all decay topologies considered in this analysis are explicitly given
 168 in Appendix H.

169 2.3 Fit implementation

170 The hadronic amplitudes are renormalized prior to the amplitude fit such that

$$\int |A_i(\mathbf{x})|^2 d\Phi_4 = 1. \quad (2.27)$$

171 This allows us to set more intuitive starting values as the amplitude coefficients are all on
 172 a comparable scale. Moreover, the total amplitudes $\mathcal{A}_f^{c(u)}(\mathbf{x})$ are renormalized on-the-fly
 173 (*i.e.* at each minimization step) such that

$$\begin{aligned} & \int \left| \mathcal{A}_f^{c(u)}(\mathbf{x}) \right|^2 d\Phi_4 = 1 \\ & \arg \left(\int \mathcal{A}_f^c(\mathbf{x})^* \mathcal{A}_f^u(\mathbf{x}) d\Phi_4 \right) = 0. \end{aligned} \quad (2.28)$$

174 As a result, the average amplitude ratio and strong phase difference between the $b \rightarrow u$ and
 175 $b \rightarrow c$ transitions can be introduced as direct fit parameters instead of derived quantities
 176 that have to be calculated from Equation 2.11 after the fit. For the differential decay rate
 177 follows:

$$\begin{aligned} \frac{d\Gamma(\mathbf{x}, t, q, f)}{e^{-\Gamma_s t} dt d\Phi_4} \propto & \left(|\mathcal{A}_f^c(\mathbf{x})|^2 + r^2 |\mathcal{A}_f^u(\mathbf{x})|^2 \right) \cosh \left(\frac{\Delta\Gamma_s t}{2} \right) \\ & + q f \left(|\mathcal{A}_f^c(\mathbf{x})|^2 - r^2 |\mathcal{A}_f^u(\mathbf{x})|^2 \right) \cos (\Delta m_s t) \\ & - 2 r \text{Re} \left(\mathcal{A}_f^c(\mathbf{x})^* \mathcal{A}_f^u(\mathbf{x}) e^{i\delta - if(\gamma - 2\beta_s)} \right) \sinh \left(\frac{\Delta\Gamma_s t}{2} \right) \\ & - 2 q f r \text{Im} \left(\mathcal{A}_f^c(\mathbf{x})^* \mathcal{A}_f^u(\mathbf{x}) e^{i\delta - if(\gamma - 2\beta_s)} \right) \sin (\Delta m_s t) \end{aligned} \quad (2.29)$$

178 This renormalization procedure was found to be crucial for the fit stability since it reduces
 179 the correlation between the a_i^c and a_i^u amplitude coefficients significantly. Due to the
 180 overall normalization, one of the complex amplitude coefficients a_i^c can be fixed to unity
 181 and since r and δ are included as fit parameters one of the complex amplitude coefficient
 182 a_i^u can be additionally fixed to unity.

183 We force strong decays in the cascade topology to have the same pattern in $b \rightarrow c$
 184 and $b \rightarrow u$ transitions by the sharing of couplings between related quasi-two-body final
 185 states. For example, given the two a_i^c parameters required for $B_s \rightarrow D_s^- K_1(1270)^+$
 186 with $K_1(1270)^+ \rightarrow \rho(770)^0 \pi^+$ and $K_1(1270)^+ \rightarrow K^*(892) \pi^+$, the amplitude $\bar{B}_s \rightarrow$
 187 $D_s^- K_1(1270)^+$ with $K_1(1270)^+ \rightarrow \rho(770)^0 \pi^+$ and $K_1(1270)^+ \rightarrow K^*(892) \pi^+$ only requires
 188 one additional global complex parameter to represent the different production processes
 189 of $B_s \rightarrow D_s^- K_1(1270)^+$ and $\bar{B}_s \rightarrow D_s^- K_1(1270)^+$, while the relative magnitude and phase
 190 of $K_1(1270)^+ \rightarrow \rho(770)^0 \pi^+$ and $K_1(1270)^+ \rightarrow K^*(892) \pi^+$ are the same regardless of
 191 the production mechanism. For this purpose, multiple decay amplitudes of a three-body
 192 resonance are defined relative to a given reference channel.

193 2.4 Validation

194 The amplitude fit is performed by using the amplitude analysis tool **MINT2**. It was
 195 previously applied to analyze $D^0 \rightarrow 4\pi$ and $D^0 \rightarrow KK\pi\pi$ decays [9] which have an
 196 identical general spin structure (*i.e.* scalar to four scalar decay) to $B_s \rightarrow D_s K\pi\pi$ decays.
 197 In the course of the $D^0 \rightarrow hhhh$ analysis, the implementation of the amplitudes were
 198 extensively cross-checked against other available tools such as **qft++** [28], **AmpGen** [21]
 199 and where possible **EVTGEN** [29]. Since no additional line shapes or spin factors are
 200 needed for this analysis, we consider the amplitude calculation as fully validated.

201 This does, however, not apply to the full time-dependent amplitude pdf which is
 202 newly implemented for this analysis. To cross-check it, we use **EVTGEN** to generate
 203 toy events with time-dependent CP violation according to the **SSD_Cp** event model [29].
 204 Since this event model does not allow for multiple interfering resonances, we generate
 205 only the decay chain $B_s \rightarrow D_s(K_1(1400) \rightarrow K^*(892)\pi)$. Table 2.1 lists the generated
 206 input parameters. The toy data set is fitted with our **MINT2** implementation of the full
 207 time-dependent amplitude pdf and the phasespace-integrated pdf. Flat decay-time and
 208 phase-space acceptances are used. The true ID of the B_s meson is used to tag the initial
 209 flavor (*i.e.* perfect tagging). For technical reasons (the extreme case of perfect resolution
 210 is currently not implemented in our fitter) we smeared the generated decay-times with a
 211 Gaussian of width 45 fs. We use a Gaussian of the same width to convolute the pdf for
 212 fitting. More details of the fit procedures are given in Secs. 9 and 10. The fit projections
 213 are shown in Figs. 2.1 and 2.2.

214 The CP coefficients $C, D, \bar{D}, S, \bar{S}$ are the fit parameters in case of the phasespace-
 215 integrated pdf, which are converted after to the fit to the physical observables r, κ, δ and γ
 216 using the **GammaCombo** package [30]. The obtained 1-CL contours are shown in Fig. 2.3.
 217 The full pdf determines r, δ and γ directly. As shown in Tab. 2.2 and 2.3, the fit results
 218 are in excellent agreement with the generated input values. The phasespace-integrated fit
 219 is, in addition, performed with the **B2DX** fitter used for the $B_s \rightarrow D_s K$ analysis yielding
 220 identical results. Note though that some parts of the **B2DX** fitter have been taken over to
 221 our **MINT2** fitter, such that the implementations are not fully independent.

222 3 Data samples and event selection

223 3.1 Stripping and Trigger selection

224 The dataset used for this analysis corresponds to 1 fb^{-1} of proton-proton collision data col-
225 lected in 2011 with a centre of mass energy $\sqrt{s} = 7 \text{ TeV}$, 2 fb^{-1} collected in 2012 with $\sqrt{s} =$
226 7 TeV and 4 fb^{-1} collected in 2015/2016/2017 with $\sqrt{s} = 13 \text{ TeV}$. Candidate $B_s^0 \rightarrow D_s K \pi \pi$
227 ($B_s^0 \rightarrow D_s \pi \pi \pi$) decays are reconstructed using the `B02DKPiPiD2HHHPIDBeauty2CharmLine`
228 (`B02DPiPiD2HHHPIDBeauty2CharmLine`) line of the `BHadronCompleteEvent` stream of
229 `Stripping21r1` (2011), `Stripping21` (2012), `Stripping24r1` (2015) and `Stripping28r1p1` (2016)
230 and `Stripping29r2` (2017). Both stripping lines employ the same selection cuts, listed in
231 Appendix A, except for the PID requirement on the bachelor kaon/pion.

232 Events that pass the stripping selection are further required to fulfill the following
233 trigger requirements: at the hardware stage, the B_s^0 candidates are required to be TOS
234 on the `L0Hadron` trigger or TIS on `L0Global`; at Hlt1, B_s^0 candidates are required to be
235 TOS on the `Hlt1TrackAllL0` (`Hlt1TrackMVA` or `Hlt1TwoTrackMVA`) trigger line for Run-I
236 (Run-II) data; at Hlt2, candidates have to be TOS on either one of the 2, 3 or 4-body
237 topological trigger lines or the inclusive ϕ trigger. More details on the used HLT lines are
238 given in Appendix A.

239 Due to a residual kinematic dependence on whether the event is triggered by `L0Hadron`
240 or not and on the data taking condition, the analysis is performed in four disjoint categories:
241 `[Run-I,L0-TOS]`, `[Run-I,L0-TIS]`, `[Run-II,L0-TOS]` and `[Run-II,L0-TIS]`, where for simplic-
242 ity we denote `L0Hadron-TOS` as `L0-TOS` and (`L0Global-TIS` and not `L0Hadron-TOS`) as
243 `L0-TIS`.

244 3.2 Offline selection

245 The offline selection, in particular the requirements on the D_s hadron, are guided by
246 the previous analyses of $B_s \rightarrow D_s K/\pi$, $B_d \rightarrow D^0 \pi$ as well as the branching fraction
247 measurement of $B_s^0 \rightarrow D_s K \pi \pi$ decays. Tables 3.1 and 3.2 summarize all selection
248 requirements which are described in the following. Throughout the note, we abbreviate
249 $B_s^0 \rightarrow D_s X_s (\rightarrow K \pi \pi)$ and $B_s^0 \rightarrow D_s X_d (\rightarrow \pi \pi \pi)$.

250 Given the high number of pp interactions per bunch crossing, a large fraction of
251 events have more than one reconstructed PV. We choose the 'best' PV to be the one
252 to which the B_s candidate has the smallest χ_{IP}^2 . In instances where the association
253 of the B_s candidate to the best PV is wrong, the decay time of this candidate will be
254 incorrect. These wrongly associated candidates are rejected by requiring that the B_s
255 χ_{IP}^2 with respect to any other PV is sufficiently higher than with respect to the best PV
256 ($\Delta\chi_{IP}^2 = \chi_{IP,\text{SECONDBEST}}^2 - \chi_{IP,\text{BEST}}^2 > 20$). Events with only a single PV are not affected.

257 In order to clean up the sample and to align the Run-I to the slightly tighter Run-II
258 stripping selection, we apply the following loose cuts to the b-hadron:

- 259 • DIRA > 0.99994
- 260 • min IP $\chi^2 < 16$ to the best PV,
- 261 • FD $\chi^2 > 100$ to the best PV,
- 262 • Vertex $\chi^2/\text{nDoF} < 8$.

263 The cut on the B_s decay-time is tightened with respect to the stripping selection ($t > 0.2$ ps)
264 because, while offline we use the decay-time determined for a DTF in which the PV position,
265 the D_s and the B_s mass are constrained, in the stripping the simple decay-time returned
266 by a kinematic fit is used. The difference between these two decay-times extends up to 0.1
267 ps, thus cutting at 0.4 ps avoids any boundary effects and simplifies the time-acceptance
268 studies. We further remove outliers with poorly estimated decay times ($\delta t < 0.15$ ps).

269 We reconstruct the $B_s^0 \rightarrow D_s h\pi\pi$ decay through three different final states of the
270 D_s meson: $D_s \rightarrow KK\pi$, $D_s \rightarrow \pi\pi\pi$ and $D_s \rightarrow K\pi\pi$. Of those, $D_s \rightarrow KK\pi$ is the
271 most prominent one, while $\mathcal{BR}(D_s \rightarrow \pi\pi\pi) \approx 0.2 \cdot \mathcal{BR}(D_s \rightarrow KK\pi)$ and $\mathcal{BR}(D_s \rightarrow$
272 $K\pi\pi) \approx 0.12 \cdot \mathcal{BR}(D_s \rightarrow KK\pi)$ holds for the others. For the $KK\pi$ final state we make
273 use of the well known resonance structure; the decay proceeds either via the narrow ϕ
274 resonance, the broader K^{*0} resonance or (predominantly) non-resonant. Within the ϕ
275 resonance region the sample is already sufficiently clean after the stripping so that we do
276 not impose additional criteria on the D_s daughters. For the K^{*0} and non-resonant regions
277 consecutively tighter requirements on the particle identification and the D_s flight-distance
278 are applied. We apply global requirements (*i.e.* independent of the D_s Dalitz-plot position)
279 for the other final states. All cuts are summarized in Table 3.1.

280 3.2.1 Phase space region

281 Due to the comparably low masses of the final state particles with respect to the B_s
282 mass, there is, in contrast to for example b-hadron to charmonia or charm decays, a
283 huge phase-space available for the $B_s^0 \rightarrow D_s K\pi\pi$ decay. For the invariant mass of
284 the $K\pi\pi$ subsystem it extends up to 3.4 GeV. It has however been observed that the
285 decay proceeds predominantly through the low lying axial vector states $K_1(1270)$ and
286 $K_1(1400)$, while the combinatorial background is concentrated at high $K\pi\pi$ invariant
287 masses ($m(K\pi\pi) > 2000$ MeV). Moreover, the strange hadron spectrum above 2 GeV
288 is poorly understood experimentally such that a reliable extraction of the strong phase
289 motion in that region is not possible. We consequently choose to limit the considered
290 phase space region to $m(K\pi\pi) < 1950$ MeV, which is right below the charm-strange
291 threshold ($B_s^0 \rightarrow D_s^+ D_s^-$).

292 **3.2.2 Physics background vetoes**

293 We veto various physical backgrounds, which have either the same final state as our
 294 signal decay, or can contribute via a single misidentification of $K \leftrightarrow \pi$, $K \leftrightarrow p$ or $\pi \leftrightarrow p$.
 295 Depending on the D_s final state different vetoes are applied in order to account for peaking
 296 backgrounds originating from charm meson or charmed baryon decays.

297 1. $D_s^- \rightarrow K^+ K^- \pi^-$

298 (a) $D^- \rightarrow K^+ \pi^- \pi^-$:

299 Possible with $\pi^- \rightarrow K^-$ misidentification, vetoed by requiring $m(K^+ K_\pi^- \pi^-) \neq$
 300 $m(D^-) \pm 40$ MeV or the K^- has to fulfill more stringent PID criteria depending
 301 on the resonant region (see Table 3.1).

302 (b) $\Lambda_c^- \rightarrow K^+ \bar{p} \pi^-$:

303 Possible with $\bar{p} \rightarrow K^-$ misidentification, vetoed by requiring $m(K^+ K_p^- \pi^-) \neq$
 304 $m(\Lambda_c^-) \pm 40$ MeV or the K^- has to fulfill more stringent PID criteria depending
 305 on the resonant region (see Table 3.1).

306 (c) $D^0 \rightarrow KK$:

307 D^0 combined with a random π can fake a $D_s \rightarrow KK\pi$ decay,

308 2. $D_s^- \rightarrow \pi^+ \pi^- \pi^-$

309 (a) $D^0 \rightarrow \pi\pi$:

310 D^0 combined with a random π can fake a $D_s \rightarrow \pi\pi\pi$ decay, vetoed by requiring
 311 both possible combinations to have $m(\pi\pi) < 1700$ MeV.

312 3. $D_s^- \rightarrow K^- \pi^+ \pi^-$

313 (a) $D^- \rightarrow \pi^- \pi^+ \pi^-$:

314 Possible with $\pi^- \rightarrow K^-$ misidentification, vetoed by requiring $m(K_\pi^- \pi^+ \pi^-) \neq$
 315 $m(D^-) \pm 40$ MeV or $\text{PIDK}(K^+) > 15$.

316 (b) $\Lambda_c^- \rightarrow \bar{p} \pi^+ \pi^-$:

317 Possible with $\bar{p} \rightarrow K^-$ misidentification, vetoed by requiring $m(K_p^- \pi^+ \pi^-) \neq$
 318 $m(\Lambda_c^-) \pm 40$ MeV or $\text{PIDK}(K^-) - \text{PIDp}(K^-) > 5$.

319 (c) $D^0 \rightarrow K\pi$:

320 D^0 combined with a random π can fake a $D_s \rightarrow K\pi\pi$ decay, vetoed by requiring
 321 both possible combinations to have $m(K\pi) < 1750$ MeV.

322 The effects of these veto cuts are illustrated in Figs. 3.1,3.2 and 3.3. To reduce cross-feed
 323 from our calibration channel into the signal channel and vice-versa we require tight PID
 324 cuts on the ambiguous bachelor track; for the signal channel we apply $\text{PIDK}(K^+) > 10$
 325 and for the calibration channel $\text{PIDK}(\pi^+) < 0$. In addition, we veto $B_s^0 \rightarrow D_s^- D_s^+$ decays
 326 which is illustrated in Fig. 3.4.

- 327 1. $X_s^+ \rightarrow K^+\pi^+\pi^-$:
- 328 (a) $B_s^0 \rightarrow D_s\pi\pi\pi$:
329 Possible with $\pi^+ \rightarrow K^+$ misidentification, suppressed with $\text{PIDK}(K^+) > 10$.
- 330 (b) $B_s^0 \rightarrow D_s^-(D_s^+ \rightarrow K^+\pi^+\pi^-)$:
331 Outside of considered phase-space region, see Sec. 3.2.1.
- 332 (c) $B_s^0 \rightarrow D_s^-(D_s^+ \rightarrow K^+K^-\pi^+)$:
333 To suppress $B_s^0 \rightarrow D_s^-K^+K^-\pi^+$ background, possible with $K^- \rightarrow \pi^-$ misiden-
334 tification, we require $\text{PIDK}(\pi^-) < 0$. In case the invariant mass of the $K^+\pi^+\pi^-$
335 system recomputed applying the kaon mass hypothesis to the pion is close to
336 the D_s mass ($m(K^+\pi^+\pi_K^-) = m(D_s) \pm 20$ MeV), we further tighten the cut to
337 $\text{PIDK}(\pi^-) < -5$.
- 338 2. $X_d^+ \rightarrow \pi^+\pi^+\pi^-$:
- 339 (a) $B_s^0 \rightarrow D_s K\pi\pi$:
340 Possible with single missID of $K^+ \rightarrow \pi^+$, suppressed with $\text{PIDK}(\pi^+) < 0$.
- 341 (b) $B_s^0 \rightarrow D_s^-(D_s^+ \rightarrow \pi^+\pi^+\pi^-)$:
342 Outside of considered phase-space region, see Sec. 3.2.1.
- 343 (c) $B_s^0 \rightarrow D_s^-(D_s^+ \rightarrow K^+\pi^-\pi^+)$:
344 Possible with single missID of $K^+ \rightarrow \pi^+$, vetoed by requiring $m(\pi^+\pi_K^+\pi^-) \neq$
345 $m(D_s) \pm 20$ MeV or $\text{PIDK}(\pi^+) < -5$ for both π^+ .

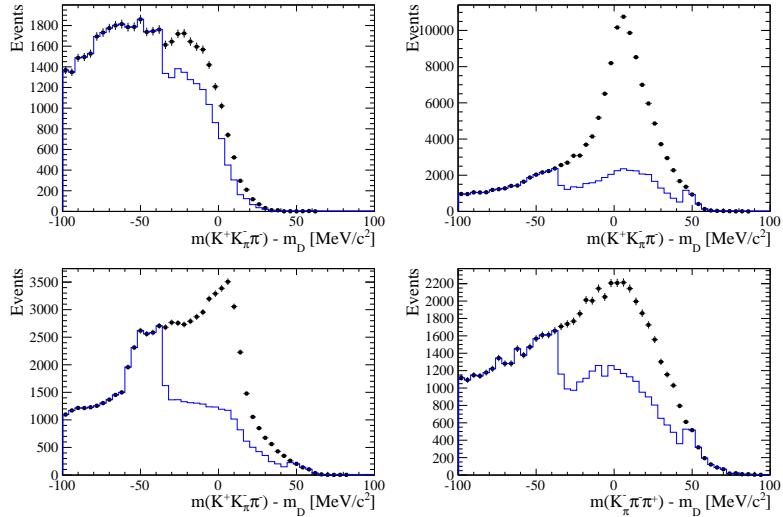

Figure 3.1: Background contributions from D^- decays where the π^- is misidentified as K^- . The D_s invariant mass is recomputed applying the pion mass hypothesis to the kaon and shown for the $D_s \rightarrow \phi\pi$, $D_s \rightarrow K^*(892)K$, $D_s \rightarrow KK\pi$ (non-resonant) and $D_s \rightarrow K\pi\pi$ final state categories from top-left to bottom-right. The distributions are shown without (black) and with (blue) the D^- -veto applied.

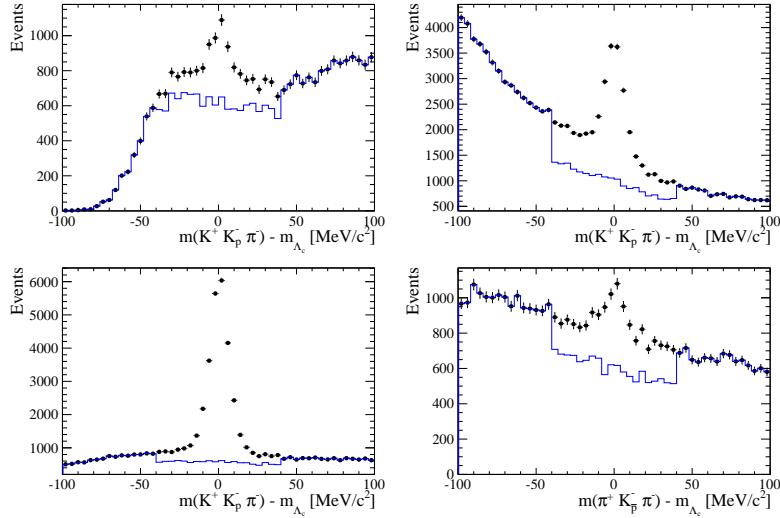

Figure 3.2: Background contributions from Λ_c decays where the \bar{p} is misidentified as K^- . The D_s invariant mass is recomputed applying the proton mass hypothesis to the kaon and shown for the $D_s \rightarrow \phi\pi$, $D_s \rightarrow K^*(892)K$, $D_s \rightarrow KK\pi$ (non-resonant) and $D_s \rightarrow K\pi\pi$ final state categories from top-left to bottom-right. The distributions are shown without (black) and with (blue) the Λ_c -veto applied.

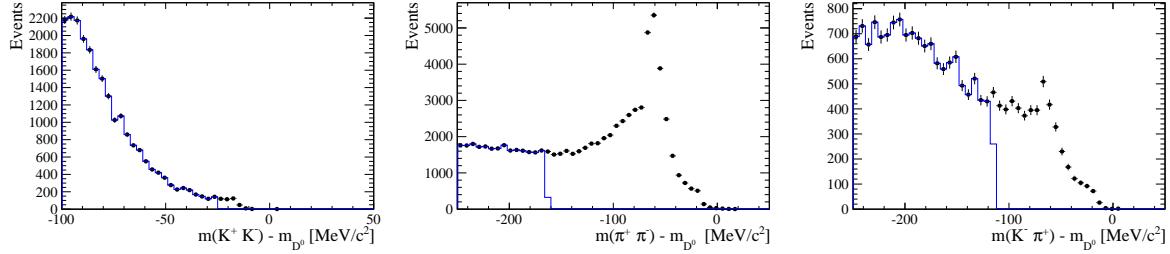

Figure 3.3: Background contributions to $D_s \rightarrow KK\pi$ (left), $D_s \rightarrow \pi\pi\pi$ (middle) and $D_s \rightarrow K\pi\pi$ (right) from $D^0 \rightarrow hh$ decays combined with a random pion. The peak at $m(\pi\pi) - m(D^0) \approx -60$ MeV ($m(K\pi) - m(D^0) \approx -60$ MeV) are due to $D^0 \rightarrow K\pi$ ($D^0 \rightarrow KK$) where a kaon is misidentified as pion.

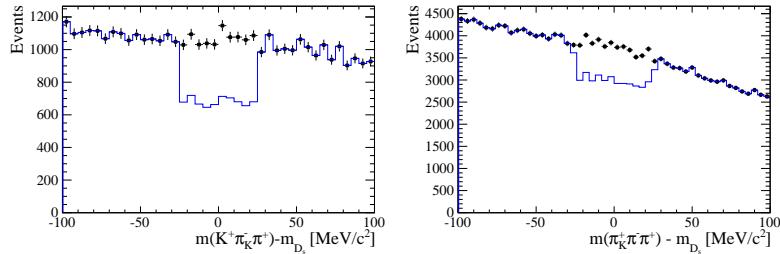

Figure 3.4: Background contributions to $B_s \rightarrow D_s K\pi\pi$ (left) and $B_s \rightarrow D_s \pi\pi\pi$ (right) from $B_s \rightarrow D_s D_s$ decays where the kaon is misidentified as pion. The $X_{s,d}$ invariant mass is recomputed applying the kaon mass hypothesis to the pion and shown without (black) and with (blue) the D_s -veto applied.

346 **3.2.3 Training of multivariate classifier**

347 The Toolkit for Multivariate Analysis (TMVA [31]) is used to train a multivariate classifier
348 (BDT with gradient boosting, BDTG) discriminating signal and combinatorial background.
349 We use $B_s \rightarrow D_s \pi\pi$ data that passes the preselection as signal proxy. The background
350 is statistically subtracted by applying `sWeights` based on the fit to the reconstructed B_s
351 mass shown in Fig. 3.5. This is a simplified version (performed in a reduced mass range)
352 of the final mass fits described in Sec. 4. The sideband data ($m(B_s) > 5500$ MeV) is used
353 as background proxy.

354 Training the classifier on a sub-sample which is supposed to be used in the final analysis
355 might cause a bias, as the classifier selects, in case of overtraining, the training events
356 more efficiently. As overtraining can not be completely avoided, we split the signal and
357 the background training samples into two disjoint subsamples according to whether the
358 event number is even or odd. We then train the classifier on the even sample and apply it
359 to the odd one, and vice-versa (cross-training).

360 The following discriminating variables are used for the BDTG training:

- 361 • logarithm of the B_s impact-parameter χ^2 , $B_s \log(\chi_{IP}^2)$
- 362 • logarithm of the cosine of the B_s direction angle, $\log(\text{DIRA})$
- 363 • fit quality of the DTF with PV constrain, χ_{DTF}^2/ndf
- 364 • logarithm of the minimal vertex quality difference for adding one extra track,
365 $\log(\Delta\chi_{add-track}^2)$
- 366 • the asymmetry between the transverse momentum of the B_s - candidate and the
367 transverse momentum of all the particles reconstructed with a cone of radius
368 $r = \sqrt{(\Delta\Phi)^2 + (\Delta\eta)^2} < 1$ rad around the B_s - candidate, $B_s A_{pT}^{\text{cone}}$
- 369 • largest ghost probability of all tracks, $\max(\text{ghostProb})$
- 370 • logarithm of the the smallest X_s daughter impact-parameter χ^2 , $X_s \log(\min(\chi_{IP}^2))$
- 371 • largest distance of closest approach of the X_s daughters, $\max(\text{DOCA})$
- 372 • cosine of the largest opening angle between the D_s and another bachelor track h_i in
373 the plane transverse to the beam, $\cos(\max \theta_{D_s h_i})$
- 374 • logarithm of the the smallest D_s daughter impact-parameter χ^2 , $D_s \log(\min(\chi_{IP}^2))$
- 375 • logarithm of the D_s flight-distance significance, $D_s \log(\chi_{FD}^2)$
- 376 • logarithm of the D_s radial flight-distance, $D_s \log(RFD)$

377 Loose cuts on the variables χ_{DTF}^2/ndf , $\Delta\chi_{add-track}^2$ and $\cos(\max \theta_{D_s h_i})$ are applied prior
378 to the training which are expected to be 100% signal efficient. Figure 3.6 shows the
379 distributions of the input variables for signal and background. As shown in Appendix B,
380 these distributions differ between data-taking period and trigger category. In particular
381 variables depending on the B_s kinematics and the event multiplicity are affected (e.g.
382 $\theta_{D_s h_i}$ or A_{pT}^{cone}). The BDTG is consequently trained separately for these categories. The
383 resulting classifier response is shown in Fig. 3.7 for each category (even and odd test
384 samples combined) and in Appendix B for each training.

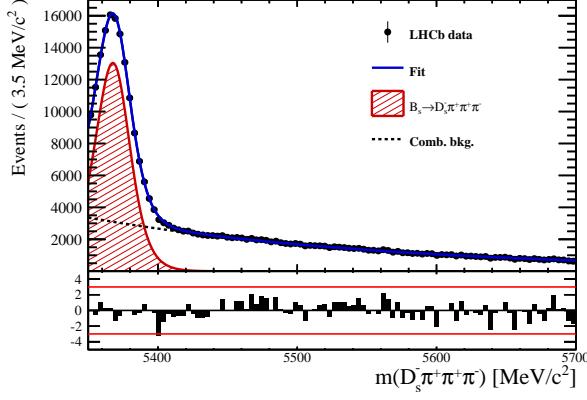

Figure 3.5: Reconstructed B_s mass for $B_s \rightarrow D_s \pi\pi\pi$ events that pass the preselection. The fitted PDF is shown in blue, the signal component in red and the background component in black.

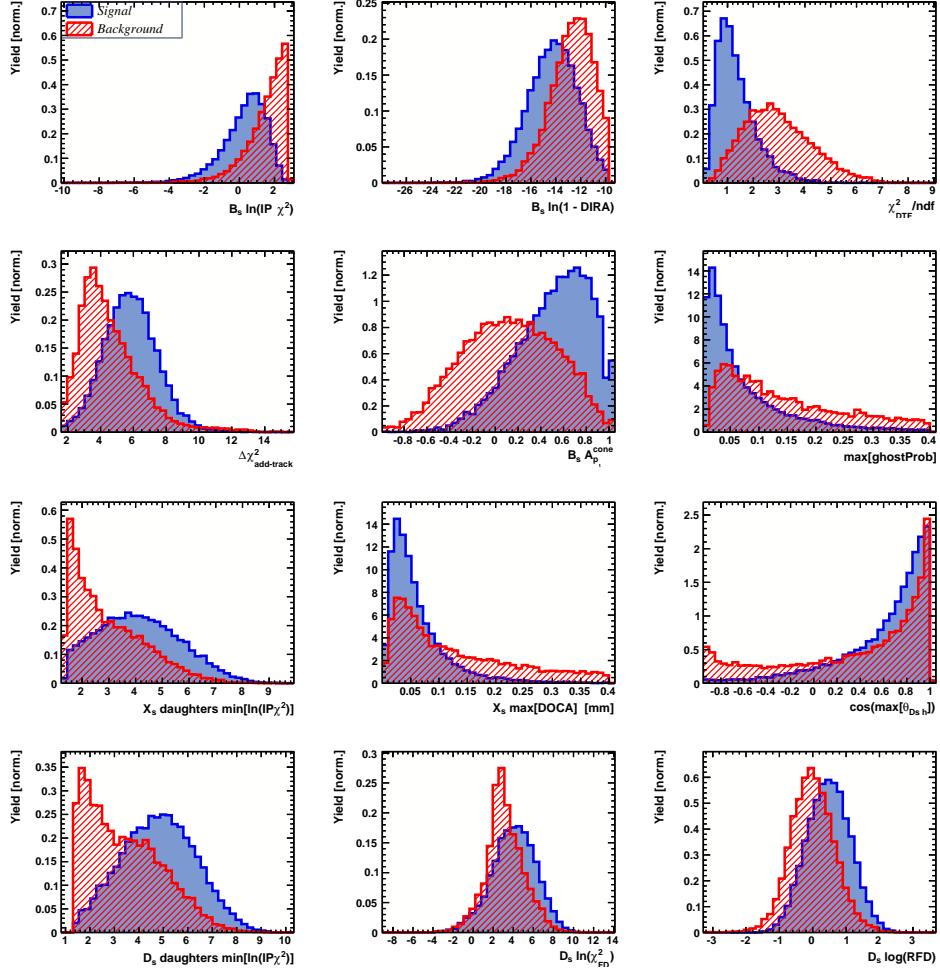

Figure 3.6: Discriminating variables used to train the BDTG for all data categories combined.

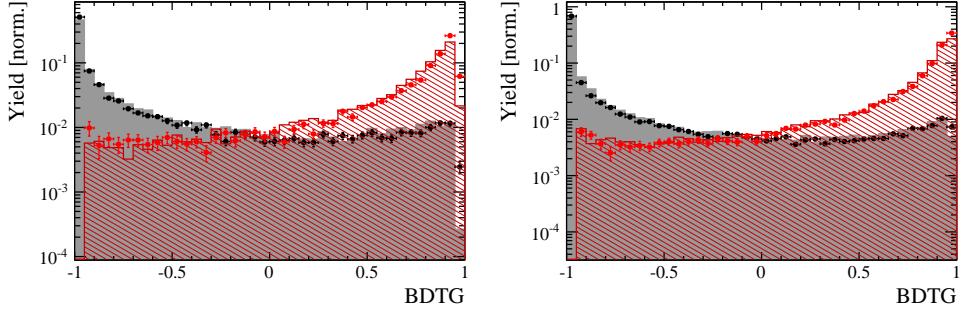

Figure 3.7: Signal (red) and background (black) distributions for the BDTG response for Run-I (left) and Run-II (right) data. Filled histograms (data points) show the BDTG response for the L0-TOS (L0-TIS) category. Even and odd test samples are combined.

3.2.4 Final selection

The cut on the BDTG output is optimized using the signal significance as figure of merit:

$$\text{FOM}(\text{BDTG}) = \frac{N_s(\text{BDTG})}{\sqrt{N_s(\text{BDTG}) + N_b(\text{BDTG})}} \quad (3.1)$$

where $N_s(\text{BDTG})$ is the $B_s \rightarrow D_s K\pi\pi$ signal yield for a given BDTG cut and $N_b(\text{BDTG})$ is the combinatorial background yield in the signal region ($m(D_s K\pi\pi) = m_{B_s} \pm 40 \text{ MeV}$). To compute the yields as function of the BDTG cut, we use the BDTG efficiencies, $\epsilon_{s,b}$, evaluated on the corresponding test samples. To fix the overall scale, it is required to know the yields at (at least) one point of the scanned range. We arbitrarily choose this fix point to be $\text{BDTG} > 0$ and perform a fit to the reconstructed B_s mass as described in Sec. 4 to obtain the yields $N_{s,b}(0)$. These yields are then efficiency corrected to calculate the yields for a given BDTG cut:

$$N_{s,b}(\text{BDTG}) = N_{s,b}(0) \cdot \frac{\epsilon_{s,b}(\text{BDTG})}{\epsilon_{s,b}(0)}. \quad (3.2)$$

Figure 3.8 shows the resulting BDTG scans for each training category.

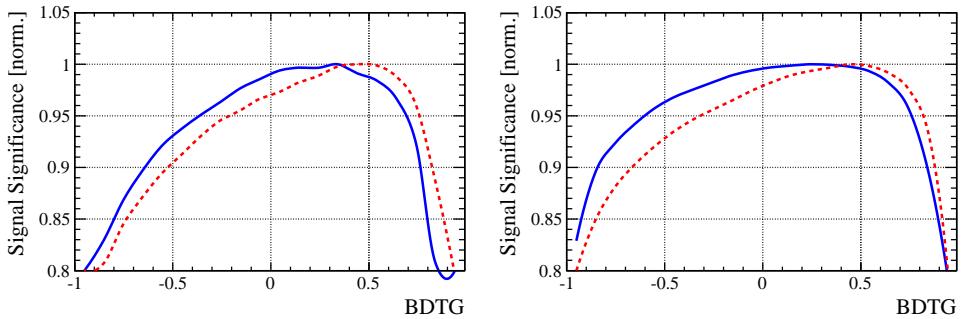

Figure 3.8: Signal significance as function of the applied cut on the BDTG response for Run-I (left) and Run-II (right) data. The scans for the L0-TOS (L0-TIS) category are shown in blue (red). The signal significance is normalized to be 1 at the optimal BDTG cut value.

396 3.3 Simulation

397 Several Monte Carlo (MC) samples are used in the analysis for acceptance and background
 398 studies. A full list of them is given in Tab. 3.3. In each case, the decay model includes
 399 a mixture of non-interfering resonances contributing to the $X_s \rightarrow K\pi\pi$ or $X_d \rightarrow \pi\pi\pi$
 400 bachelor system and a non-resonant (phase-space) component. All MC samples are
 401 generated using Pythia8, reconstructed using Reco14c, Reco15 and Reco16 for Run-I, 15
 402 and 16 data and selected using the same criteria as in data.

Table 3.3: List of simulated samples used in the analysis.

Decay	Event Type	Sim	Statistics				Filter
			11	12	15	16	
$B_s \rightarrow (D_s \rightarrow KK\pi)K\pi\pi$	13266007	08i	1.2 M	1.2 M	-	-	Generator Level

4 Yields determination

An extended unbinned maximum likelihood fit to the reconstructed B_s mass of the selected events is performed in order to determine the signal and background yields. The invariant mass $m(D_s h\pi\pi)$ is determined from a DTF constraining the mass of the D_s to the PDG value and the position of the PV. The probability density functions (PDFs) used to describe the signal and background components are described in the following.

Due to different mass resolutions, we perform the invariant mass fits simultaneously for each data-taking period and each trigger category. We further introduce four D_s final state categories: $D_s \rightarrow \phi\pi$, $D_s \rightarrow K^*(892)\pi$, $D_s \rightarrow \pi\pi\pi$ and $D_s \rightarrow Kh\pi$ to account for different signal purities. The $D_s \rightarrow Kh\pi$ category combines the two D_s decay channels with the lowest statistics: $D_s \rightarrow KK\pi$ (non-resonant) and $D_s \rightarrow K\pi\pi$. This amounts to 16 categories in total.

4.1 Signal model

The signal B_s -mass distribution of both $B_s^0 \rightarrow D_s K\pi\pi$ and $B_s^0 \rightarrow D_s \pi\pi\pi$ is modeled using a Johnson's SU function [32], which results from a variable transformation of a normal distribution to allow for asymmetric tails:

$$\mathcal{J}(x|\mu, \sigma, \nu, \tau) = \frac{e^{-\frac{1}{2}r^2}}{2\pi \cdot c \cdot \sigma \cdot \tau \cdot \sqrt{z^2 + 1}} \quad (4.1)$$

$$r = -\nu + \frac{\operatorname{asinh}(z)}{\tau} \quad (4.2)$$

$$z = \frac{x - (\mu - c \cdot \sigma \cdot e^\tau \sinh(\nu \cdot \tau))}{c \cdot \tau} \quad (4.3)$$

$$c = \frac{e^{\tau^2} - 1}{2\sqrt{e^{\tau^2} \cdot \cosh(2\nu \cdot \tau) + 1}}. \quad (4.4)$$

It is conveniently expressed in terms of the central moments up to order four: The mean of the distribution μ , the standard deviation σ , the skewness ν and the kurtosis τ . The tail parameters ν and τ are fixed to the values obtained by a fit to the invariant mass distribution of simulated events shown in Fig 4.1. To account for differences between simulation and real data, linear scaling factors for the mean μ and width σ are determined in the fit to $B_s^0 \rightarrow D_s \pi\pi\pi$ data and later fixed in the fit to $B_s^0 \rightarrow D_s K\pi\pi$ decays. The scale factors are determined separately for each data-taking period and each trigger category.

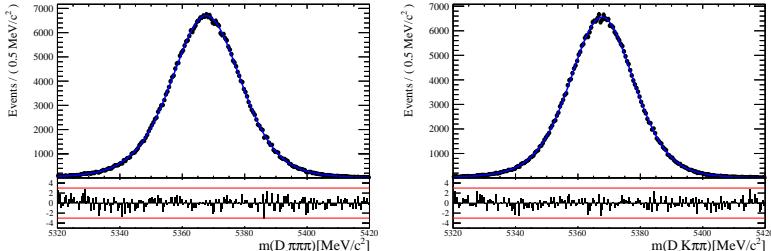

Figure 4.1: Invariant mass distributions of simulated (left) $B_s^0 \rightarrow D_s \pi\pi\pi$ and (right) $B_s^0 \rightarrow D_s K\pi\pi$ events. A fit with a Johnson's SU PDF is overlaid.

426 **4.2 Background models**

427 After the full selection the following residual background components have to be accounted
428 for:

429

430 **Combinatorial background**

431 The combinatorial background is described by a second order polynomial, whose
432 parameters are determined, for each D_s final state separately, in the fit to data. For
433 systematic studies an exponential PDF is used.

434

435 **Peaking B_d background**

436 Decays of B_d mesons into the $D_s h\pi\pi$ final state are described by the B_s signal PDF
437 where the mean is shifted by the known mass difference $m_{B_s} - m_{B_d}$ [12].

438

439 **Partially reconstructed background**

440 Partially reconstructed $B_s^0 \rightarrow D_s^* \pi\pi\pi$ decays, with $D_s^* \rightarrow D_s \gamma$ or $D_s^* \rightarrow D_s \pi^0$, are expected
441 to be peaking lower than signal in the $m(D_s \pi\pi\pi)$ spectrum with large tails due to the
442 momentum carried away by the not reconstructed π^0 or γ . An empirical description for
443 the shape of this contribution is derived from a $B_s^0 \rightarrow D_s^* \pi\pi\pi$ MC sample subject to
444 the nominal $B_s^0 \rightarrow D_s \pi\pi\pi$ selection. Figure 4.2 (top) shows the respective reconstructed
445 $m(D_s \pi\pi\pi)$ distribution. A sum of three bifurcated Gaussian functions (*i.e.* Gaussian
446 functions with different widths on the left and the right side of the maximum value) is used
447 to describe it. In the fit to data, all parameters are fixed to the ones obtained from MC
448 except for the parameter which describes the width of the right tail of the distribution to
449 account for data-simulation differences in mass resolution. The equivalent $B_s^0 \rightarrow D_s^* K\pi\pi$
450 component contributing to the $B_s^0 \rightarrow D_s K\pi\pi$ data sample is described by the same PDF
451 with the right tail fixed to the $B_s^0 \rightarrow D_s \pi\pi\pi$ result.

452 Contributions from $B^0 \rightarrow D_s^* K\pi\pi$ decays are modeled with the $B_s^0 \rightarrow D_s^* K\pi\pi$ PDF
453 shifted by $m_{B_s^0} - m_{B^0}$.

454

455 **Misidentified background**

456 A small fraction of $B_s \rightarrow D_s^- \pi^+ \pi^+ \pi^-$ and $B_s^0 \rightarrow D_s^* \pi^+ \pi^+ \pi^-$ decays, where one of the
457 pions is misidentified as a kaon, contaminate the $B_s^0 \rightarrow D_s K^+ \pi^+ \pi^-$ sample. To determine
458 the corresponding background shapes, we use simulated events passing the nominal
459 selection except for the PID cuts on the bachelor π^+ tracks. The **PIDCalib** package
460 is used to determine the p_T, η -dependent $\pi^+ \rightarrow K^+$ misidentification probability for
461 each pion. We change the particle hypothesis from pion to kaon for the pion with the
462 higher misidentification probability and recompute the invariant B_s^0 mass, $m(D_s^- \pi_K^+ \pi^+ \pi^-)$.
463 Similarly, the invariant masses $m(\pi_K^+ \pi^+ \pi^-)$ and $m(\pi_K^+ \pi^-)$ are recomputed and required
464 to be within the considered phasespace region. The background distributions are shown
465 in Fig. 4.2 (middle, bottom) and modeled by the sum of three Crystal Ball functions.

466 The expected yield of misidentified $B_s^0 \rightarrow D_s\pi\pi\pi$ ($B_s^0 \rightarrow D_s^*\pi^+\pi^+\pi^-$) candidates in
 467 the $B_s^0 \rightarrow D_sK\pi\pi$ sample is computed by multiplying the fake rate (within the considered
 468 B_s mass range) of $0.63 \pm 0.01\%$ ($0.55 \pm 0.02\%$) for Run-I and $0.33 \pm 0.01\%$ ($0.24 \pm 0.01\%$)
 469 for Run-II by the $B_s^0 \rightarrow D_s\pi\pi\pi$ ($B_s^0 \rightarrow D_s^*\pi^+\pi^+\pi^-$) yield as determined in the mass
 470 fit to the $B_s^0 \rightarrow D_s\pi\pi\pi$ data sample. The yields are corrected for the $\text{PID}(\pi^+) < 0$
 471 requirement which has an efficiency of $77.1 \pm 0.1\%$ for Run-I and $81.0 \pm 0.1\%$ for Run-II
 472 data. The $B_s^0 \rightarrow D_s^*\pi^+\pi^+\pi^-$ yield is additionally corrected for the efficiency of the cut
 473 $m(D_sK\pi\pi) > 5200 \text{ MeV}$ evaluated on MC. In the fit to data, the misidentified background
 474 yields are fixed to the predicted ones.

475 We consider the $B_s^0 \rightarrow D_sK\pi\pi$ and $B_s^0 \rightarrow D_s^*K\pi\pi$ components contributing to the
 476 $B_s^0 \rightarrow D_s\pi\pi\pi$ data sample to be negligible due to the low branching fractions and the
 477 tight PID cuts on the bachelor pions.

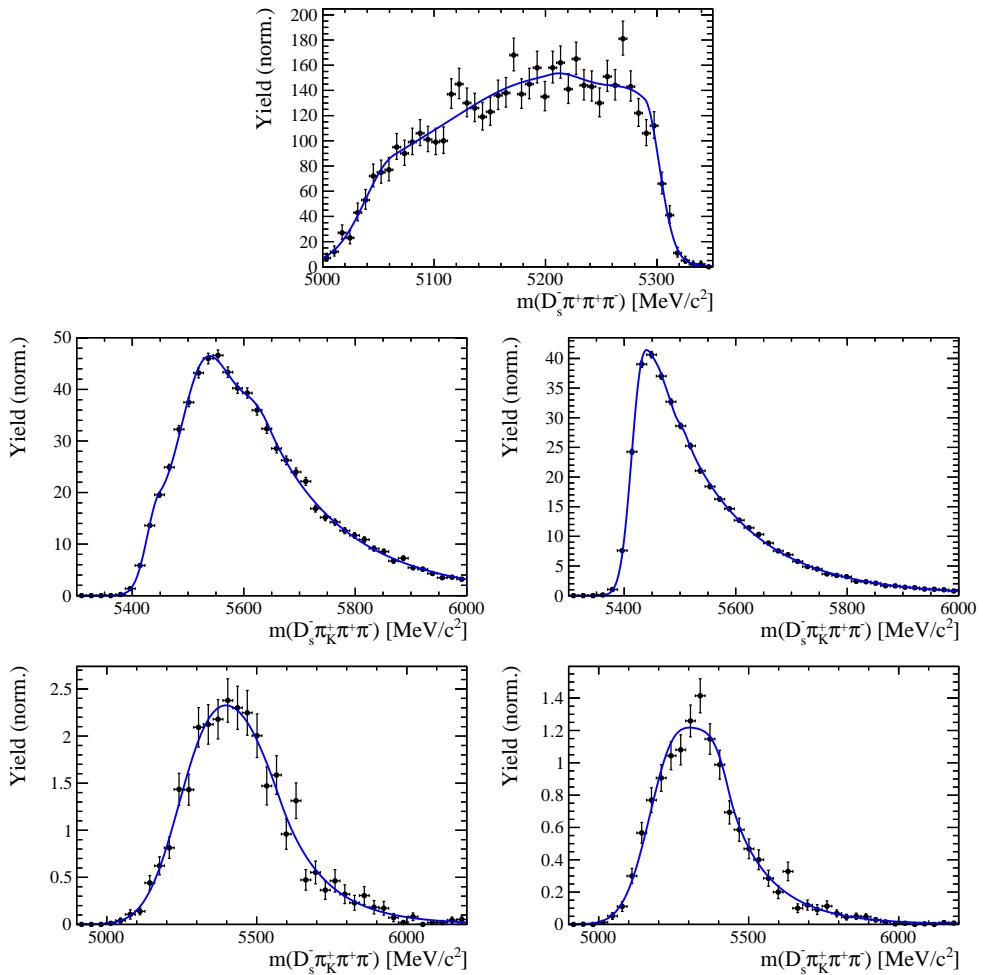

Figure 4.2: Top: Invariant mass distribution of simulated $B_s^0 \rightarrow D_s^*\pi\pi\pi$ events, where the γ/π^0 is excluded from the reconstruction. Middle: Invariant mass distribution of simulated $B_s^0 \rightarrow D_s\pi\pi\pi$ events for Run-I (left) and Run-II (right), where one of the pions is reconstructed as a kaon taking the misidentification probability into account. Bottom: Invariant mass distribution for simulated $B_s^0 \rightarrow D_s^*\pi\pi\pi$ events for Run-I (left) and Run-II (right), where the γ/π^0 from the D_s^* is excluded from reconstruction and one of the pions is reconstructed as a kaon taking the misidentification probability into account. The fitted PDFs are shown in blue.

4.3 Results

Figure 4.3 shows the invariant mass distribution for $B_s^0 \rightarrow D_s\pi\pi\pi$ and $B_s^0 \rightarrow D_sK\pi\pi$ candidates passing all selection criteria. The projections for all categories of the simultaneous fit are shown in Appendix C. The integrated signal and background yields are listed in Tables 4.1 and 4.2.

$D_s^- \rightarrow \pi^+\pi^-\pi^-$	864 ± 41

483 5 Decay-time Resolution

484 The observed oscillation of B mesons is prone to dilution, if the detector resolution is
 485 of similar magnitude as the oscillation period. In the B_s^0 system, considering that the
 486 measured oscillation frequency of the B_s^0 [33] and the average LHCb detector resolution [34]
 487 are both $\mathcal{O}(50 \text{ fs}^{-1})$, this is the case. Therefore, it is crucial to correctly describe the
 488 decay time resolution in order to avoid a bias on the measurement of time dependent CP
 489 violation. Since the time resolution depends on the particular event, especially the decay
 490 time itself, the sensitivity on γ can be significantly improved by using an event dependent
 491 resolution model rather than an average resolution. For this purpose, we use the per-event
 492 decay time error that is estimated based on the uncertainty obtained from the global
 493 kinematic fit of the momenta and vertex positions (DTF) with additional constraints on
 494 the PV position and the D_s mass. In order to apply it correctly, it has to be calibrated.
 495 The raw decay time error distributions for $B_s^0 \rightarrow D_s\pi\pi\pi$ signal candidates are shown in
 496 Figure 5.1 for Run-I and Run-II data. Significant deviations between the two different
 497 data taking periods are observed due to the increase in center of mass energy from Run-I
 498 to Run-II, as well as (among others) new tunings in the pattern and vertex reconstruction.
 499 The decay time error calibration is consequently performed separately for both data taking
 500 periods.

501 For Run-I data, we use the calibration from the closely related $B_s^0 \rightarrow D_s K$ analysis
 502 which was performed on a data sample of prompt- D_s candidates combined with a random
 503 pion track from the PV. We verify the portability to our decay channel on MC.

504 For Run-II data, a new lifetime unbiased stripping line (LTUB) has been implemented
 505 which selects prompt- D_s candidates combined with random $K\pi\pi$ tracks from the PV.

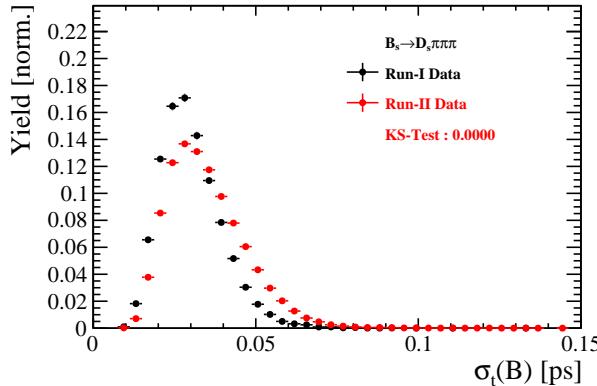

Figure 5.1: Distribution of the decay time error for $B_s^0 \rightarrow D_s\pi\pi\pi$ signal candidates for Run-I (black) and Run-II (red) data (sWeighted).

506 5.1 Calibration for Run-I data

507 For simulated $B_s^0 \rightarrow D_s K \pi\pi$ events, the spread of the differences between reconstructed
 508 decay time and true decay time, $\Delta t = t - t_{true}$, is a direct measure of the decay time
 509 resolution. The sum of two Gaussian pdfs with common mean but different widths is used
 510 to fit the distribution of the decay time difference Δt as shown in Fig. 5.2. The effective
 511 damping of the CP amplitudes due to the finite time resolution is described by the dilution
 512 \mathcal{D} . In the case of infinite precision, there would be no damping and therefore $\mathcal{D} = 1$ would
 513 hold, while for a resolution that is much larger than the B_s^0 oscillation frequency, \mathcal{D} would
 514 approach 0. For a double-Gaussian resolution model, the dilution is given by [35]

$$515 \quad \mathcal{D} = f_1 e^{-\sigma_1^2 \Delta m_s^2 / 2} + (1 - f_1) e^{-\sigma_2^2 \Delta m_s^2 / 2}, \quad (5.1)$$

515 where σ_1 and σ_2 are the widths of the Gaussians, f_1 is the relative fraction of events
 516 described by the first Gaussian relative to the second and Δm_s is the oscillation frequency
 517 of B_s^0 mesons. An effective single Gaussian width is calculated from the dilution as,

$$518 \quad \sigma_{eff} = \sqrt{(-2/\Delta m_s^2) \ln \mathcal{D}}, \quad (5.2)$$

518 which converts the resolution into a single-Gaussian function with an effective resolution
 519 that causes the same damping effect on the magnitude of the B_s oscillation. For the Run-I
 520 $B_s^0 \rightarrow D_s K \pi\pi$ MC sample the effective average resolution is found to be $\sigma_{eff} = 39.1 \pm 0.3$ fs.

521 To analyze the relation between the per-event decay time error δ_t and the actual
 522 resolution σ_t , the simulated $B_s^0 \rightarrow D_s K \pi\pi$ sample is divided into equal-statistics slices of
 523 δ_t . For each slice, the effective resolution is determined as described above. Details of the
 524 fit results in each slice are shown in appendix D. Figure 5.2 shows the obtained values
 525 for σ_{eff} as a function of the per-event decay time error σ_t . To account for the variable
 526 binning, the bin values are not placed at the bin center but at the weighted mean of the
 527 respective per-event-error bin. A linear function is used to parametrize the distribution.
 528 The obtained values are

$$529 \quad \sigma_{eff}^{MC}(\sigma_t) = (0.0 \pm 0.0) \text{ fs} + (1.232 \pm 0.010) \sigma_t \quad (5.3)$$

529 where the offset is fixed to 0. For comparison, the calibration function found for $B_s^0 \rightarrow D_s K$
 530 MC is also shown in Figure 5.2 [35]:

$$531 \quad \sigma_{eff}^{D_s K, MC}(\sigma_t) = (0.0 \pm 0.0) \text{ fs} + (1.201 \pm 0.013) \sigma_t. \quad (5.4)$$

531 Due to the good agreement between the scale factors for $B_s^0 \rightarrow D_s K$ and $B_s^0 \rightarrow D_s K \pi\pi$
 532 MC, we conclude that the resolution calibration for $B_s^0 \rightarrow D_s K$ data:

$$533 \quad \sigma_{eff}^{D_s K}(\sigma_t) = (10.26 \pm 1.52) \text{ fs} + (1.280 \pm 0.042) \sigma_t \quad (5.5)$$

533 can be used for our analysis. The following calibration functions were used in the
 534 $B_s^0 \rightarrow D_s K$ analysis to estimate the systematic uncertainty on the decay-time resolution:

$$535 \quad \sigma_{eff}^{D_s K}(\sigma_t) = (-0.568 \pm 1.570) \text{ fs} + (1.243 \pm 0.044) \sigma_t \quad (5.6)$$

$$535 \quad \sigma_{eff}^{D_s K}(\sigma_t) = (0.0 \pm 0.0) \text{ fs} + (1.772 \pm 0.012) \sigma_t \quad (5.7)$$

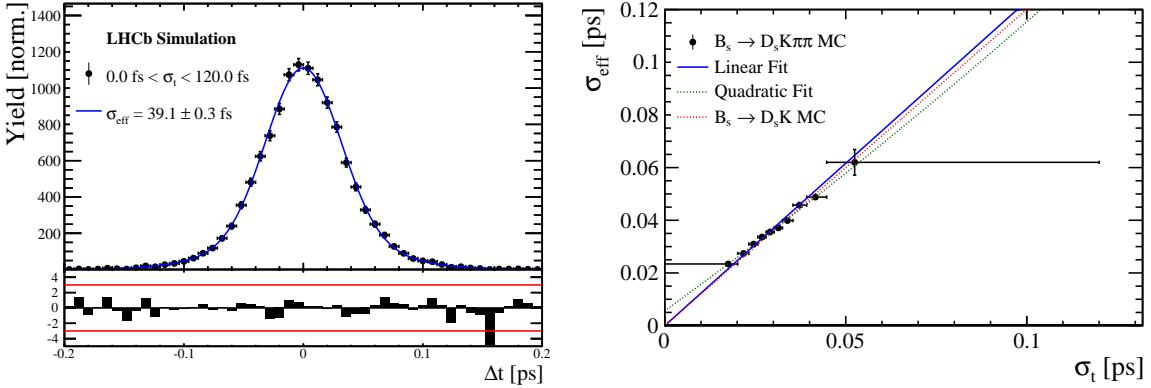

Figure 5.2: (Left) Difference of the true and measured decay time of $B_s^0 \rightarrow D_s K\pi\pi$ MC candidates. (Right) The measured resolution σ_{eff} as function of the per-event decay time error estimate σ_t for $B_s \rightarrow D_s K\pi\pi$ MC (Run-I). The fitted calibration curve is shown in blue.

5.2 Calibration for Run-II data

For the resolution calibration of Run-II data, a sample of promptly produced D_s candidates is selected using the B02DsKPiPiLTUBD2HHHBeauty2CharmLine stripping line. This lifetime-unbiased stripping line does not apply selection requirements related to lifetime or impact parameter, allowing for a study of the resolution. In order to reduce the rate of this sample it is pre-scaled in the stripping. Each D_s candidate is combined with a random kaon track and two random pion tracks which originate from the PV to obtain a sample of fake B_s candidates with a known true decay-time of $t_{\text{true}} = 0$. The difference of the measured decay time, t , of these candidates with respect to the true decay time is attributed to the decay time resolution.

The offline selection of the fake B_s candidates is summarized in Tab. 5.1. The selection is similar than the one for real data with the important difference that the D_s candidate is required to come from the PV by cutting on the impact parameter significance. Even after the full selection, a significant number of multiple candidates is observed. These are predominantly fake B_s candidates that share the same D_s candidate combined with different random tracks from the PV. We select one of these multiple candidates randomly which retains approximately 20% of the total candidates. As can be seen in Figure K.3, the shapes of the distributions of the unscaled decay time error σ_t for data taken in 2016 and 2017 are significantly different. Therefore, the scaling of the decay time error is treated separately for 2015+2016 and 2017 data. The invariant mass distribution of the selected D_s candidates is shown in Fig. 5.3. To separate true D_s candidates from random combinations, the sPlot method is used to statistically subtract combinatorial background from the sample.

Figure 5.4 and 5.5 show the sWeighted decay-time distributions for fake B_s candidates from 2016 and 2017 data, respectively. Similar as in the previous section, the decay-time distribution is fitted with a double-Gaussian resolution model in slices of the per-event decay time error. Since some D_s candidates might actually originate from true B_s decays, the decay-time distribution of the fake B_s candidates might show a bias towards positive decay times. Therefore, we determine the decay-time resolution from the negative decay-time distribution only. Details of the fit results in each slice are shown in appendix D.

⁵⁶⁶ The resulting calibration functions are:

$$\sigma_{eff}^{Data,16}(\sigma_t) = (11.6 \pm 1.6) \text{ fs} + (0.877 \pm 0.040) \sigma_t \quad (5.8)$$

⁵⁶⁷

$$\sigma_{eff}^{Data,17}(\sigma_t) = (6.5 \pm 1.4) \text{ fs} + (0.961 \pm 0.036) \sigma_t \quad (5.9)$$

⁵⁶⁸ For 2016, the result is in good agreement with the one obtained for the $B_s \rightarrow J/\psi\phi$
⁵⁶⁹ (Run-II) analysis that uses 2016 data [36].

$$\sigma_{eff}^{J/\psi\phi}(\sigma_t) = (12.25 \pm 0.33) \text{ fs} + (0.8721 \pm 0.0080) \sigma_t \quad (5.10)$$

Table 5.1: Offline selection requirements for fake B_s candidates from promptly produced D_s candidates combined with random prompt $K\pi\pi$ bachelor tracks. The PID and veto cuts depending on the D_s final state and Dalitz plot position are the same as in Table. 3.1.

	Description	Requirement
$B_s \rightarrow D_s K\pi\pi$	χ^2_{vtx}/ndof	< 8
	χ^2_{DTF}/ndof	< 15
	t	< 0 ps
$D_s \rightarrow hh$	χ^2_{vtx}/ndof	< 5
	DIRA	> 0.99994
	χ^2_{FD}	> 9
	p_T	> 1800 MeV
	χ^2_{IP}	< 9
	$\chi^2_{IP}(h)$	> 5
Wrong PV veto	nPV = 1 min($\Delta\chi^2_{IP}$) > 20	
$X_s \rightarrow K\pi\pi$	$\chi^2_{IP}(h)$	< 40
	PIDK(K)	> 10
	PIDK(π)	< 5
	isMuon(h)	False
All tracks	p_T	> 500 MeV

Data taken in 2017.

570 6 Acceptance

571 6.1 MC corrections

572 6.1.1 Truth matching of simulated candidates

573 We use the `BackgroundCategory` tool to truth match our simulated candidates. Candidates
 574 with background category (`BKGCAT`) 20 or 50 are considered to be true signal. Background
 575 category 60 is more peculiar since it contains both badly reconstructed signal candidates
 576 and ghost background. This is due to the fact that the classification algorithms identifies
 577 all tracks for which less than 70% of the reconstructed hits are matched to generated
 578 truth-level quantities as ghosts. In particular for signal decays involving many tracks (as
 579 in our case), this arbitrary cutoff is not 100% efficient. Moreover, the efficiency is expected
 580 to depend on the kinematics which would lead to a biased acceptance determination if
 581 candidates with `BKGCAT`= 60 would be removed. We therefore include `BKGCAT`= 60 and
 582 statistically subtract the ghost background by using the `sPlot` technique. The `sWeights`
 583 are calculated from a fit to the reconstructed B_s mass. The signal contribution is modeled
 584 as described in Sec. 4.1 and the background with a polynomial. The fit is performed
 585 simultaneously in two categories; the first includes events with `BKGCAT` = 20 or 50 and
 586 the second events with `BKGCAT` = 60. To account for the different mass resolution we
 587 use a different σ for each category, while the mean and the tail parameters are shared
 588 between them. The background component is only included for the second category.

589 A significant fraction of 7% of the true signal candidates are classified as ghosts, while
 590 only 20% of the events classified with `BKGCAT`= 60 are indeed genuine ghosts.

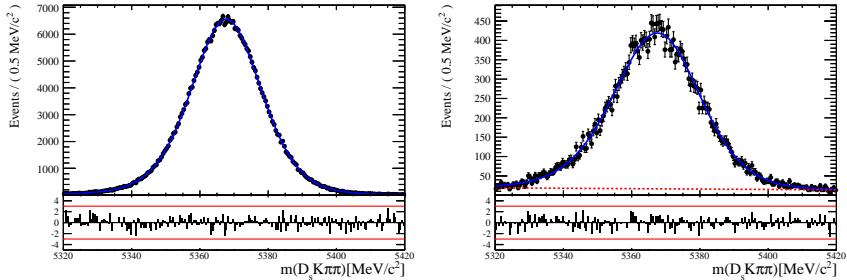

Figure 6.1: The reconstructed B_s mass distribution for simulated $B_s \rightarrow D_s K\pi\pi$ decays
 classified with `BKGCAT` = 20 or 50 (left) and `BKGCAT` = 60 (right) after the full selection.

591 6.1.2 Correction of data-simulation differences

592 For the evaluation of phase space efficiency and to a lesser extend also the decay-time
 593 efficiency we rely on simulated data as discussed in the following sections. A number
 594 of data-driven corrections are applied to the MC samples to account for known data-
 595 simulation differences. The MC sample is reweighted to match the three-dimensional
 596 p_T , η and track multiplicity distribution observed on real data. These corrections are
 597 derived from the calibration channel $B_s \rightarrow D_s \pi\pi\pi$ and applied to both the signal and
 598 calibration channel MC samples. The distributions before and after reweighting are shown
 599 in Appendix J. We use the `PIDCorr` tool to correct the simulated PID responses based on
 600 PID calibration samples [37].

601 6.2 Decay-time acceptance

602 The decay-time distribution of the B_s^0 mesons is sculpted due to the geometry of the LHCb
 603 detector and the applied selection cuts, which are described in Section 3. In particular, any
 604 requirement on the flight distance, the impact parameter or the direction angle (DIRA)
 605 of the B_s^0 mesons, as well as the direct cut on the proper-time, will lead to a decay-time
 606 dependent efficiency $\epsilon(t)$.

607 We use a combination of control channels to derive the acceptance function $\epsilon(t)$,
 608 because for $B_s^0 \rightarrow D_s K\pi\pi$ decays the decay-time acceptance is strongly correlated with
 609 the CP -observables which we aim to measure. Therefore, extracting the CP -observables
 610 and the acceptance shape at the same time is not possible. A fit to the decay-time
 611 distribution of $B_s^0 \rightarrow D_s \pi\pi\pi$ candidates is performed and the obtained acceptance shape
 612 is corrected for the small difference observed between the $B_s^0 \rightarrow D_s K\pi\pi$ and $B_s^0 \rightarrow D_s \pi\pi\pi$
 613 MC samples. In addition, we include the control channel $B^0 \rightarrow D_s K\pi\pi$ to increase
 614 the statistical precision. A simultaneous fit to the four datasets ($B_s^0 \rightarrow D_s \pi\pi\pi$ data,
 615 $B^0 \rightarrow D_s K\pi\pi$ data, $B_s^0 \rightarrow D_s K\pi\pi$ MC and $B_s^0 \rightarrow D_s \pi\pi\pi$ MC) is performed to allow for
 616 a straightforward propagation of uncertainties. In each case, a PDF of the following form

$$\mathcal{P}(t, \delta t) = \left[e^{-\Gamma t} \cdot \cosh\left(\frac{\Delta\Gamma t'}{2}\right) \otimes \mathcal{R}(t - t', \delta t) \right] \cdot \epsilon(t), \quad (6.1)$$

617 is used to describe the decay-time distribution. For real data, the values for $\Gamma_{s,d}$ and
 618 $\Delta\Gamma_{s,d}$ are fixed to the latest HFLAV results [38], while for simulated data, the generated
 619 values are used. A single Gaussian resolution function $\mathcal{R}(t - t', \delta t)$ is used where the
 620 decay-time error estimate is scaled with the respective calibration functions determined in
 621 Sec. 5. Each decay-time acceptance $\epsilon(t)$ is modeled using cubic splines, allowing for the
 622 analytical computation of the decay-time integrals appearing in the PDF [39]. The splines
 623 are parametrized by so-called knots (t_0, t_1, \dots, t_N) which determine their boundaries. Two
 624 knots are located by default at the lower and upper edge of the interval allowed for the
 625 decay time, the remaining ones are chosen such that there is an approximately equal
 626 amount of data in-between two consecutive knots. In the basis of cubic b-splines, $b_i(t)$,
 627 the acceptance is then constructed as:

$$\epsilon(t) = \sum_{i=0}^N v_i b_i(t) \quad (6.2)$$

628 where the spline coefficients v_i are determined from the fit. We fix coefficient v_{N-1} to unity
 629 in order to normalize the overall acceptance function. To stabilize the upper decay-time
 630 acceptance, v_N is fixed by a linear extrapolation from the two previous coefficients:

$$v_N = v_{N-1} + \frac{v_{N-2} - v_{N-1}}{t_{N-2} - t_{N-1}} \cdot (t_N - t_{N-1}). \quad (6.3)$$

631 It was found that at least $N = 6$ knots are necessary for a sufficient fit quality.

Three distinct splines are used in the following combinations to describe the acceptances for the four datasets:

- $B_s^0 \rightarrow D_s K\pi\pi$ MC: $\epsilon_{D_s K\pi\pi}^{MC}(t)$
- $B_s^0 \rightarrow D_s \pi\pi\pi$ MC: $\epsilon_{D_s \pi\pi\pi}^{MC}(t) = R(t) \cdot \epsilon_{D_s K\pi\pi}^{MC}(t)$
- $B_s^0 \rightarrow D_s \pi\pi\pi$ data: $\epsilon_{D_s \pi\pi\pi}^{Data}(t) = R(t) \cdot \epsilon_{D_s K\pi\pi}^{Data}(t)$
- $B^0 \rightarrow D_s K\pi\pi$ data: $\epsilon_{D_s K\pi\pi}^{Data}(t)$

where $\epsilon_{D_s K\pi\pi}^{MC}(t)$ represents the acceptance in $B_s^0 \rightarrow D_s K\pi\pi$ MC, $R(t)$ represents the ratio of acceptances in $B_s^0 \rightarrow D_s \pi\pi\pi$ and $B_s^0 \rightarrow D_s K\pi\pi$ MC and the final acceptance in $B_s^0 \rightarrow D_s K\pi\pi$ data is represented by $\epsilon_{D_s K\pi\pi}^{Data}(t)$.

The acceptances are determined separately for each data-taking period and each trigger category as discussed in more detail in Appendix E. The fit results are shown in Figs. 6.2 to 6.5 and the fitted parameters are summarized in Tables 6.1 to 6.4.

Table 6.1: Time acceptance parameters for events in category [Run-I,L0-TOS].

Knot position	Coefficient	$B_s^0 \rightarrow D_s K\pi\pi$ data	$B_s^0 \rightarrow D_s K\pi\pi$ MC	Ratio

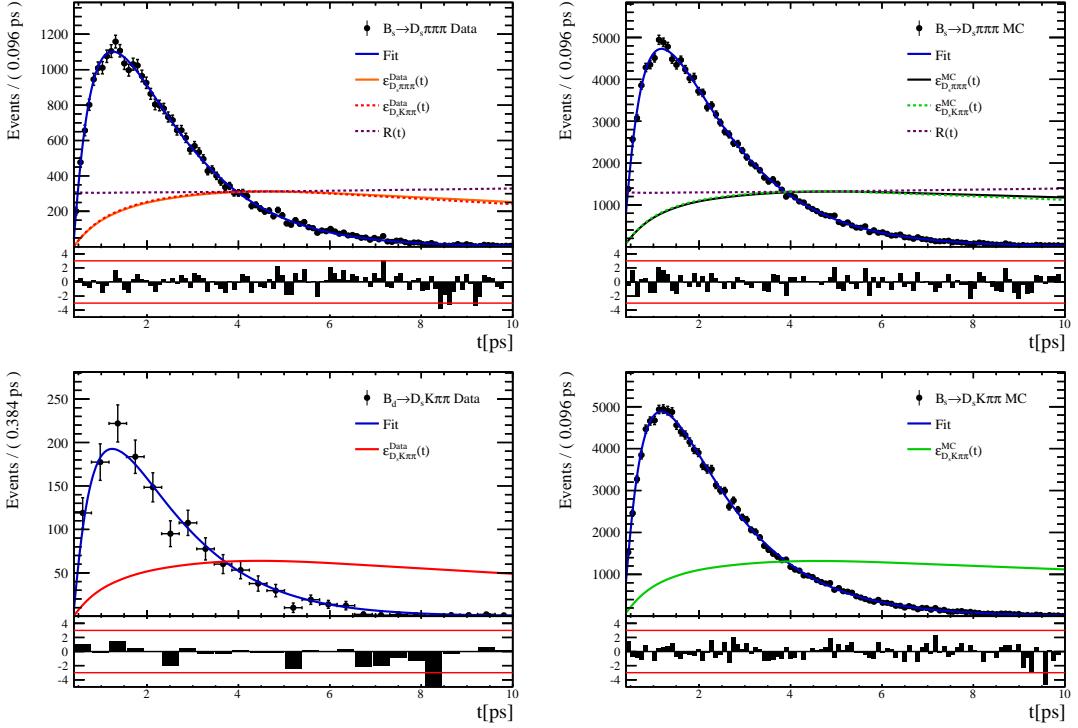

Figure 6.5: Decay-time fit projections for $B_s^0 \rightarrow D_s \pi\pi\pi$ data (top-left), $B_s^0 \rightarrow D_s \pi\pi\pi$ MC (top-right), $B^0 \rightarrow D_s K\pi\pi$ data (bottom-left) and $B_s^0 \rightarrow D_s K\pi\pi$ MC (bottom-right) in category [Run-II,L0-TIS]. The respective acceptance function is overlaid in an arbitrary scale.

644 6.3 Phase space acceptance

645 The signal PDF used for the full time-dependent amplitude fit can be written in terms of
 646 the differential decay rate from Equation 2.29 as

$$\mathcal{P}(\mathbf{x}, t, g, f) = \frac{\left(\frac{d\Gamma(\mathbf{x}, t, q, f)}{dt d\Phi_4} \right) \cdot \epsilon(\mathbf{x}) \cdot \epsilon(t)}{\int \sum_{q,f} \left(\frac{d\Gamma(\mathbf{x}, t, q, f)}{dt d\Phi_4} \right) \cdot \epsilon(\mathbf{x}) \cdot \epsilon(t) dt d\Phi_4} \quad (6.4)$$

647 where $\epsilon(\mathbf{x})$ is the phase-space efficiency. Note that the efficiency in the numerator appears
 648 as an additive constant in the log \mathcal{L} that does not depend on any fit parameters such that it
 649 can be ignored. However, the efficiency function still enters via the normalization integrals.
 650 In contrast to the time integrals which can be performed analytically as discussed in
 651 Sec. 6.2, the phase-space integrals are determined numerically. For this purpose, we use
 652 simulated events generated with **EVTGEN**, pass them through the full detector simulation
 653 and apply the same selection criteria as for data in order to perform the MC integrals. As
 654 an example, the integral of the total $b \rightarrow c$ amplitude squared can be approximated as

$$\int |\mathcal{A}_f^c(\mathbf{x})|^2 \epsilon(\mathbf{x}) d\Phi_4 \approx \frac{1}{N_{MC}} \sum_k^{N_{MC}} \frac{|\mathcal{A}_f^c(\mathbf{x}_k)|^2}{|A'(\mathbf{x}_k)|^2} \quad (6.5)$$

655 where A' labels the amplitude model used for the generation and x_k is the k -th MC
 656 event. As a result, the phase-space efficiency can be included in the fit without explicitly
 657 modeling it. The size of the fully selected MC sample ($N_{MC} = 380k$) is more than 70 times
 658 larger as the data sample which results in an integral precision smaller than 0.2%. The
 659 efficiency projections are shown in Fig. 6.6 for visualization purposes only. As discussed
 660 in Appendix F, the phase space efficiency differs significantly among L0-trigger categories
 661 while the differences are small between the data-taking periods and negligible between
 662 the D_s final states. To account for this, the MC events are scaled such that the relative
 663 proportions of the four categories [Run-I,L0-TOS], [Run-I,L0-TIS], [Run-II,L0-TOS] and
 664 [Run-II,L0-TIS] are the same as observed on the $B_s \rightarrow D_s K\pi\pi$ data sample.

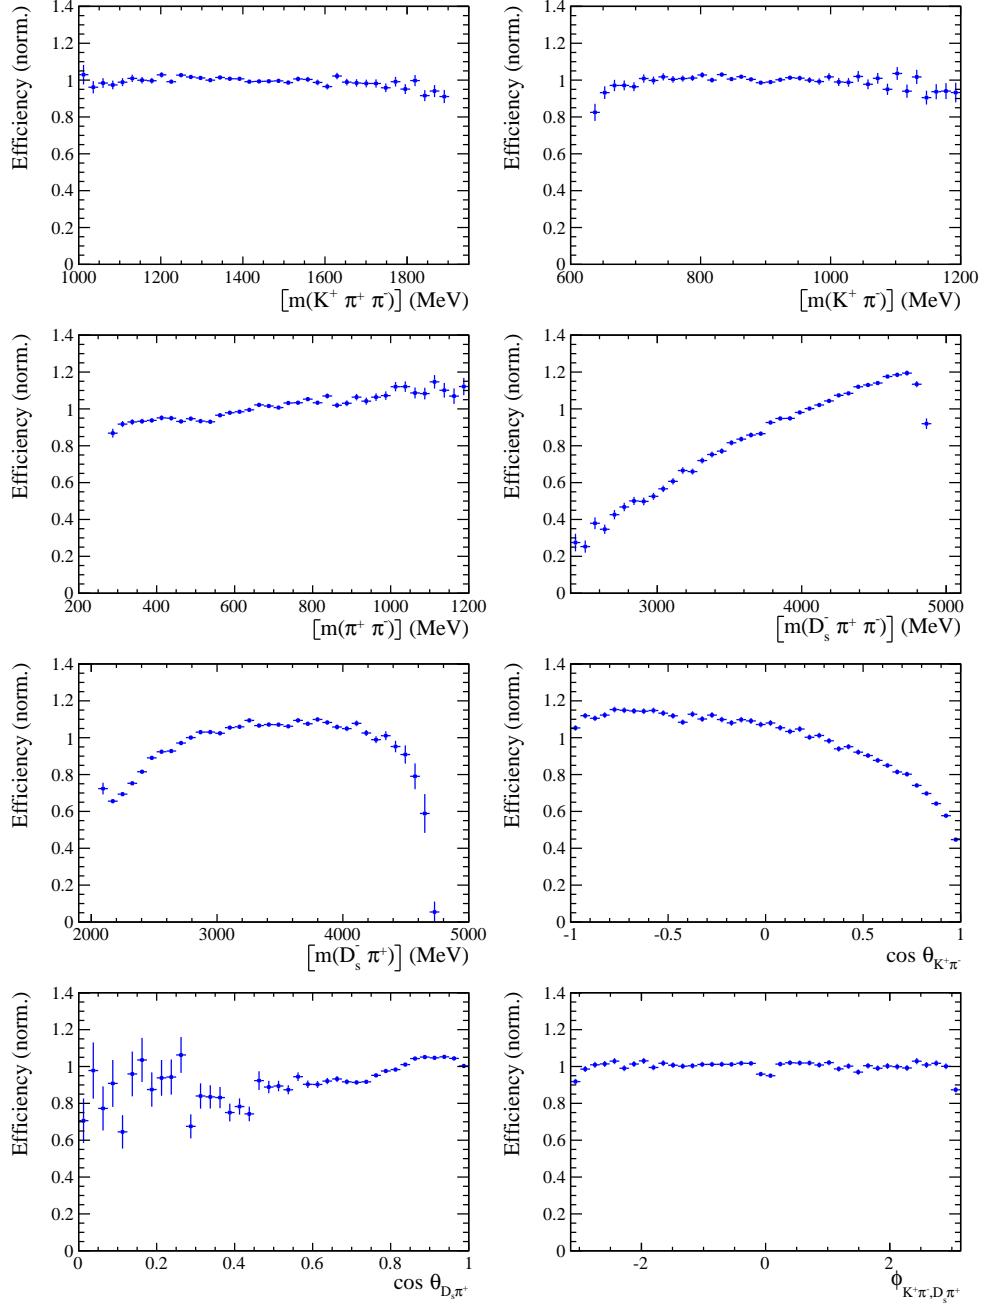

Figure 6.6: Efficiency variation as a function of the phase-space variables obtained from the ratio of selected and generated MC events.

665 7 Flavour Tagging

666 To identify the initial flavour state of the B_s^0 meson, a number of flavour tagging algorithms
 667 are used that either determine the flavour of the non-signal b-hadron produced in the
 668 event (opposite site, OS [40]) or use particles produced in the fragmentation of the signal
 669 candidate B_s^0/\bar{B}_s^0 (same side, SS [41]). For the same side, the algorithm searching for the
 670 charge of an additional kaon that accompanies the fragmentation of the signal candidate is
 671 used (SS-Kaon). For the opposite site, five different taggers are chosen: the algorithms that
 672 use the charge of an electron or a muon from semi-leptonic B decays (OS- e,μ), the tagger
 673 that uses the charge of a kaon from a $b \rightarrow c \rightarrow s$ decay chain (OS-Kaon), the algorithm
 674 which reconstructs opposite-side charm hadrons from a number of decay channels (OS-c)
 675 and the algorithm that determines the B_s^0/\bar{B}_s^0 candidate flavour from the charge of a
 676 secondary vertex, reconstructed from the OS b decay product (OS-VtxCharge).

677 Every tagging algorithm is prone to misidentify the signal candidate at a certain
 678 mistag rate ω . This might be caused by particle misidentification, flavour oscillation
 679 of the neutral opposite site B-meson or by tracks that are wrongly picked up from the
 680 underlying event. An imperfect determination of the B_s^0 production flavor dilutes the
 681 observed CP asymmetry by a factor $D_{tag} = 1 - 2\omega$. This means that the statistical
 682 precision, with which the CP asymmetry can be measured, scales as the inverse square
 683 root of the effective tagging efficiency:

$$\epsilon_{eff} = \epsilon_{tag}(1 - 2\omega)^2, \quad (7.1)$$

684 where ϵ_{tag} is the fraction of tagged candidates.

685 For each B_s^0/\bar{B}_s^0 candidate, the tagging algorithms provide, besides a flavour tag
 686 $q = 1, -1, 0$ (for an initial B_s^0 , \bar{B}_s^0 or no tag), a prediction for the mistag probability η
 687 based on the output of multivariate classifiers. These are trained on either simulated or
 688 **sWeighted** samples of flavour specific control channels ($B_s^0 \rightarrow D_s^- \pi^+$ (SS algorithm) and
 689 $B^+ \rightarrow J/\psi K^+$ (OS algorithms)) and are optimized for highest ϵ_{eff} on data. Utilizing
 690 flavour-specific final states, the estimated mistag η of each tagger has to be calibrated to
 691 match the actual mistag probability ω . For the calibration, a linear model

$$\omega(\eta) = p_0 + p_1 \cdot (\eta - \langle \eta \rangle), \quad (7.2)$$

692 is used where $\langle \eta \rangle$ is the average estimated mistag probability. A perfectly calibrated
 693 tagger would lead to $\omega(\eta) = \eta$ and one would expect $p_1 = 1$ and $p_0 = \langle \eta \rangle$. Due to the
 694 different interaction cross-sections of oppositely charged particles, the tagging calibration
 695 parameters depend on the initial state flavour of the B_s^0 . Therefore, the flavour asymmetry
 696 parameters Δp_0 , Δp_1 and $\Delta \epsilon_{tag}$ are introduced.

697 7.1 OS tagger combination

698 First, the OS electron, muon, kaon, charm and the secondary vertex charge taggers are
 699 individually calibrated and then combined into a single OS-Combo tagger using the
 700 **EspressoPerformanceMonitor** tool. We choose the flavour specific decay $B_s \rightarrow D_s \pi\pi\pi$ as
 701 calibration mode since it is very similar to the signal decay $B_s \rightarrow D_s K\pi\pi$. The calibration
 702 is performed separately for Run-I and Run-II data. The OS-c tagger is not included for
 703 Run-I data since the statistics is too low. Where available the latest Run-II tuning is
 704 used for Run-II data, otherwise the Run-I tuning of the taggers is used. Figures 7.1 and
 705 7.2 show the fitted calibration functions and Tables 7.1 and 7.2 list the measured tagging
 706 performances. The tagging calibration parameters are listed in Appendix G.

Table 7.1: The flavour tagging performances for the used OS taggers for Run-I data.

Tagger	ϵ	ω	$\epsilon\langle D^2 \rangle = \epsilon(1 - 2\omega)^2$
OS μ	$(8.713 \pm 0.206)\%$	$(28.893 \pm 0.180(\text{stat}) \pm 2.291(\text{cal}))\%$	$(1.553 \pm 0.045(\text{stat}) \pm 0.337(\text{cal}))\%$
OS e	$(3.201 \pm 0.129)\%$	$(28.792 \pm 0.363(\text{stat}) \pm 3.611(\text{cal}))\%$	$(0.576 \pm 0.030(\text{stat}) \pm 0.196(\text{cal}))\%$
OS K	$(32.230 \pm 0.342)\%$	$(38.451 \pm 0.093(\text{stat}) \pm 1.145(\text{cal}))\%$	$(1.719 \pm 0.033(\text{stat}) \pm 0.341(\text{cal}))\%$
Vertex Charge	$(21.855 \pm 0.302)\%$	$(35.712 \pm 0.091(\text{stat}) \pm 1.474(\text{cal}))\%$	$(1.785 \pm 0.033(\text{stat}) \pm 0.368(\text{cal}))\%$

Table 7.2: The flavour tagging performances for the used OS taggers for Run-II data.

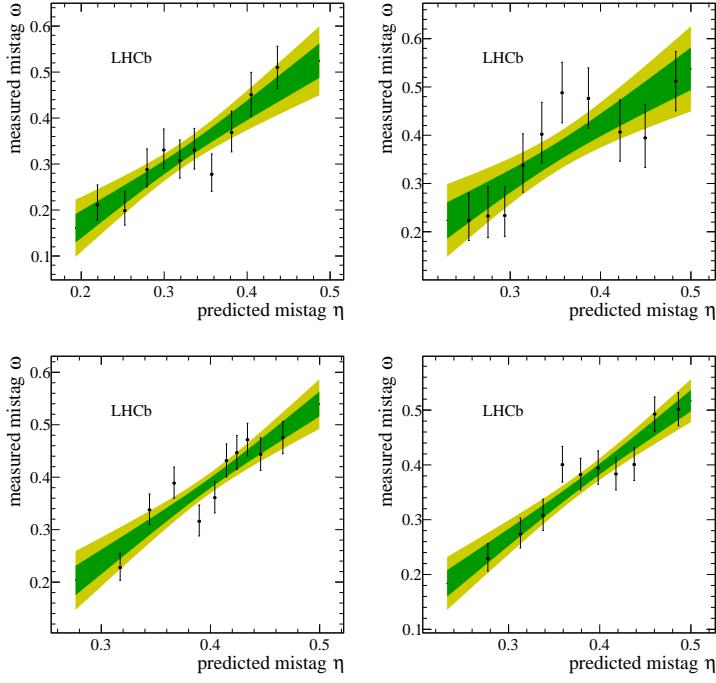

Figure 7.1: Predicted versus measured mistag probability for the (top left) OS muon, (top right) OS electron, (bottom left) OS kaon and (bottom right) OS vertex charge tagger for Run-I. A linear fit, including the 1σ and 2σ error bands is overlaid for each tagger.

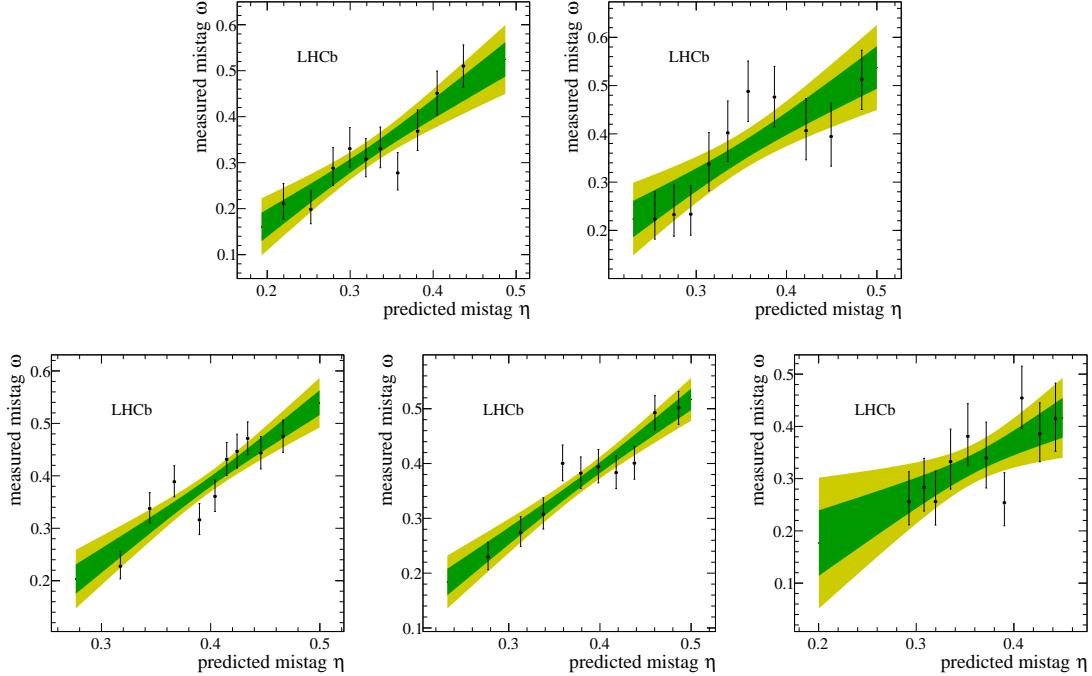

Figure 7.2: Predicted versus measured mistag probability for the (top left) OS muon, (top right) OS electron, (bottom left) OS kaon, (bottom middle) OS vertex charge and (bottom right) OS charm tagger for Run-II. A linear fit, including the 1σ and 2σ error bands is overlaid for each tagger.

7.2 Tagging performance

The OS-Combo and SS-Kaon taggers are calibrated simultaneously by fitting the $B_s \rightarrow D_s \pi\pi\pi$ decay-time distribution as discussed in Sec. 9. In this fit, the predicted mistag probabilities η_{OS} and η_{SS} , shown Fig. 7.3 for $B_s \rightarrow D_s \pi\pi\pi$ and $B_s \rightarrow D_s K\pi\pi$ data, are included as per-event observables, effectively giving a larger weight to the events that have a lower mistag probability. The tagger responses are combined into a single response on an event-by-event basis during the fit. Tables 7.3 and 7.4 report the tagging performances for the OS and SS combination considering three mutually exclusive categories of tagged events: OS only, SS only and both OS and SS. The tagging calibration parameters are listed in Table 9.1.

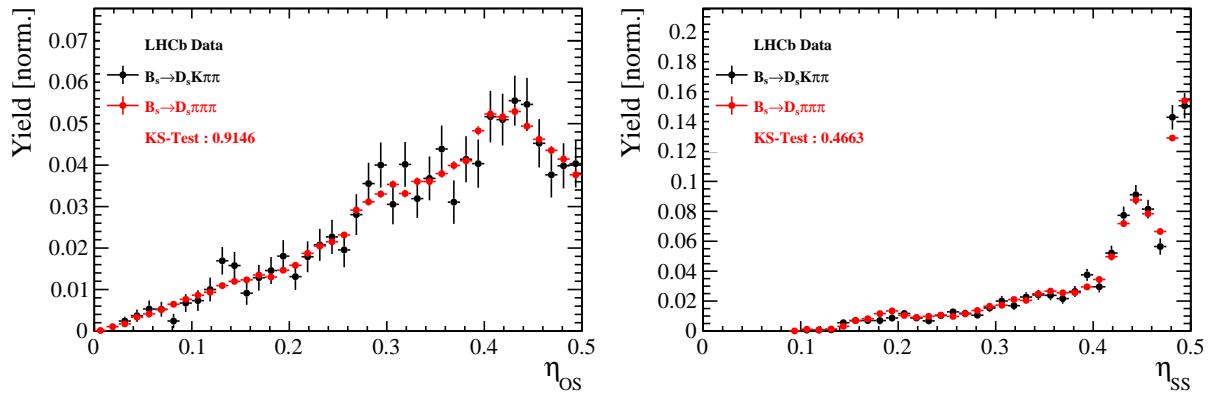

Figure 7.3: Distributions of the predicted mistag η for the OS combination (left) and the SS kaon tagger (right) for signal candidates in the $B_s^0 \rightarrow D_s K\pi\pi$ (black) and $B_s^0 \rightarrow D_s \pi\pi\pi$ (red) data samples.

Table 7.3: The flavour tagging performances for only OS tagged, only SS tagged and both OS and SS tagged events for Run-I data.

717 8 Production and Detection Asymmetries

718 8.1 B_s Production Asymmetry

719 The production rates of b and \bar{b} hadrons in pp collisions are not expected to be identical,
720 therefore this effect must be taken into account when computing CP asymmetries. The
721 production asymmetry for B_s mesons is defined as:

$$A_p(B_s^0) = \frac{\sigma(\bar{B}_s^0) - \sigma(B_s^0)}{\sigma(\bar{B}_s^0) + \sigma(B_s^0)} \quad (8.1)$$

722 where σ are the corresponding production cross-section. This asymmetry was measured
723 by LHCb in pp collisions at $\sqrt{s} = 7$ TeV and $\sqrt{s} = 8$ TeV by means of a time-dependent
724 analysis of $B_s \rightarrow D_s^- \pi^+$ decays [42]. The results in bins of p_T and η of the B_s meson
725 are shown in Table 8.1. To correct for the different kinematics of $B_s \rightarrow D_s^- \pi^+$ and
726 $B_s^0 \rightarrow D_s K\pi\pi$ decays, the measured B_s production asymmetries $A_p(p_T, \eta)$ are folded with
727 the sWeighted p_T, η distribution of our signal channel. The resulting effective production
728 asymmetries are:

$$A_p(B_s^0)_{2011} = (-0.506 \pm 1.90)\% \quad (8.2)$$

$$A_p(B_s^0)_{2012} = (-0.164 \pm 1.30)\% \quad (8.3)$$

$$A_p(B_s^0)_{\text{Run-I}} = (-0.045 \pm 1.04)\%. \quad (8.4)$$

729 As for Run-II data no measurement is available yet, we determine the production asym-
730 metry from $B_s \rightarrow D_s \pi\pi\pi$ data together with the tagging parameters.

Table 8.1: B_s production asymmetries in kinematic bins for 2011 and 2012 data. [42]

731 8.2 $K^-\pi^+$ Detection Asymmetry

732 The presented measurement of the CKM-angle γ using $B_s^0 \rightarrow D_s K\pi\pi$ decays is sensitive to
 733 a possible charge asymmetry of the kaon. Kaons are known to have a nuclear cross-section
 734 which is asymmetrically dependent on the sign of their charge. It is indispensable to
 735 determine the charge asymmetry of the kaon, as fitting without taking this effect into
 736 account would introduce a 'fake' CP violation. Instead of determining the single track
 737 detection asymmetry of a kaon, it is found that the combined two track asymmetry of a
 738 kaon-pion pair is much easier to access [43]. Therefore, the two track asymmetry defined
 739 as

$$A^{det}(K^-\pi^+) = \frac{\epsilon^{det}(K^-\pi^+) - \epsilon^{det}(K^+\pi^-)}{\epsilon^{det}(K^-\pi^+) + \epsilon^{det}(K^+\pi^-)}, \quad (8.5)$$

740 is used.

741 This asymmetry can be measured from the difference in asymmetries in the $D^+ \rightarrow$
 742 $K^-\pi^+\pi^+$ and $D^+ \rightarrow K_s^0\pi^+$ modes [44]:

$$\begin{aligned} A^{det}(K^-\pi^+) &= \frac{N(D^+ \rightarrow K^-\pi^+\pi^+) - N(D^- \rightarrow K^+\pi^-\pi^-)}{N(D^+ \rightarrow K^-\pi^+\pi^+) + N(D^- \rightarrow K^+\pi^-\pi^-)} \\ &\quad - \frac{N(D^+ \rightarrow K_s^0\pi^+) - N(D^- \rightarrow K_s^0\pi^-)}{N(D^+ \rightarrow K_s^0\pi^+) + N(D^- \rightarrow K_s^0\pi^-)} \\ &\quad - A(K^0), \end{aligned} \quad (8.6)$$

743 where possible CP violation in the $D^+ \rightarrow K_s^0\pi^+$ mode is predicted to be smaller than
 744 10^{-4} in the Standard Model [45]. The asymmetry in the neutral kaon system, $A(K^0)$, has
 745 to be taken into account as a correction.

746 We use a dedicated LHCb tool to determine $A^{det}(K^-\pi^+)$ for all data taking periods
 747 used in this analysis. A detailed description can be found in [44]. The tool provides
 748 large calibration samples of $D^\pm \rightarrow K^\pm\pi^\pm\pi^\pm$ and $D^\pm \rightarrow K_s^0\pi^\pm$ decays, which are used to
 749 determine the asymmetry following Eq. 8.6. Several weighting steps are performed to
 750 match the kinematics of the calibration samples to our signal decay sample:

751 First, weights are assigned to the K^\pm and π^\pm of the $D^\pm \rightarrow K^\pm\pi^\pm\pi^\pm$ sample, using
 752 p, η of the K^\pm and p_T, η of the π^\pm from our $B_s^0 \rightarrow D_s K\pi\pi$ signal decay. Then, weights
 753 are assigned to the D^\pm (p_T, η) and the π^\pm (p_T) of the $D^\pm \rightarrow K_s^0\pi^\pm$ sample to match
 754 the corresponding, weighted distributions of the $D^\pm \rightarrow K^\pm\pi^\pm\pi^\pm$ sample. In a last
 755 step, weights are assigned to match the bachelor pions ϕ distributions between the two
 756 calibration samples.

757 After the samples are weighted, fits are performed to the invariant
 758 $m(K^-\pi^+\pi^+)/m(K^+\pi^-\pi^-)$ and $m(K_s^0\pi^+)/m(K_s^0\pi^-)$ distributions to determine
 759 $A^{det}(K^-\pi^+)$. The PDFs used to describe the invariant mass distributions consist of
 760 gaussian functions for the signal component and exponentials describing the residual
 761 background.

762 The detection asymmetry is determined separately for every year and (since it is a
 763 charge asymmetry effect) magnet polarity. Serving as an example for Run-I and Run-
 764 II, the fits used to determine $N(D^+ \rightarrow K^-\pi^+\pi^+)/N(D^- \rightarrow K^+\pi^-\pi^-)$ and $N(D^+ \rightarrow$
 765 $K_s^0\pi^+)/N(D^- \rightarrow K_s^0\pi^-)$ for 2011, magnet up data and 2015, magnet up data are shown
 766 in Fig. 8.1 and 8.2 respectively. The obtained values of $A^{det}(K^-\pi^+) + A(K^0)$ for all years
 767 and polarities are shown in Table 8.2.

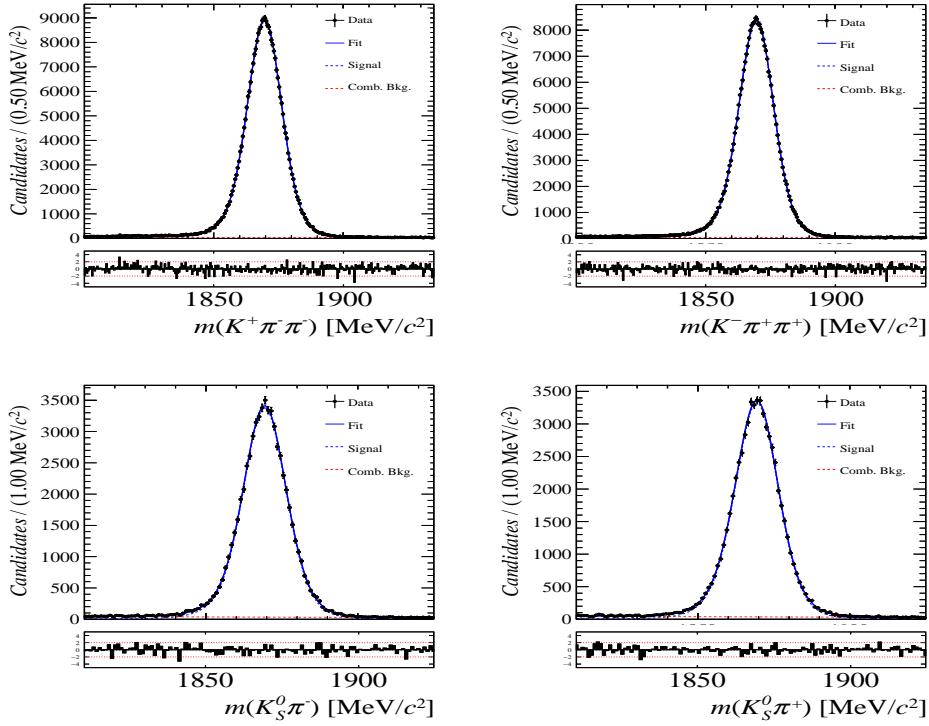

Figure 8.1: Distributions of the invariant mass of (top) $D^\pm \rightarrow K^\pm \pi^\pm \pi^\pm$ and (bottom) $D^\pm \rightarrow K_s^0 \pi^\pm$ candidates for Run-I data from the calibration samples. A fit described in the text is overlaid.

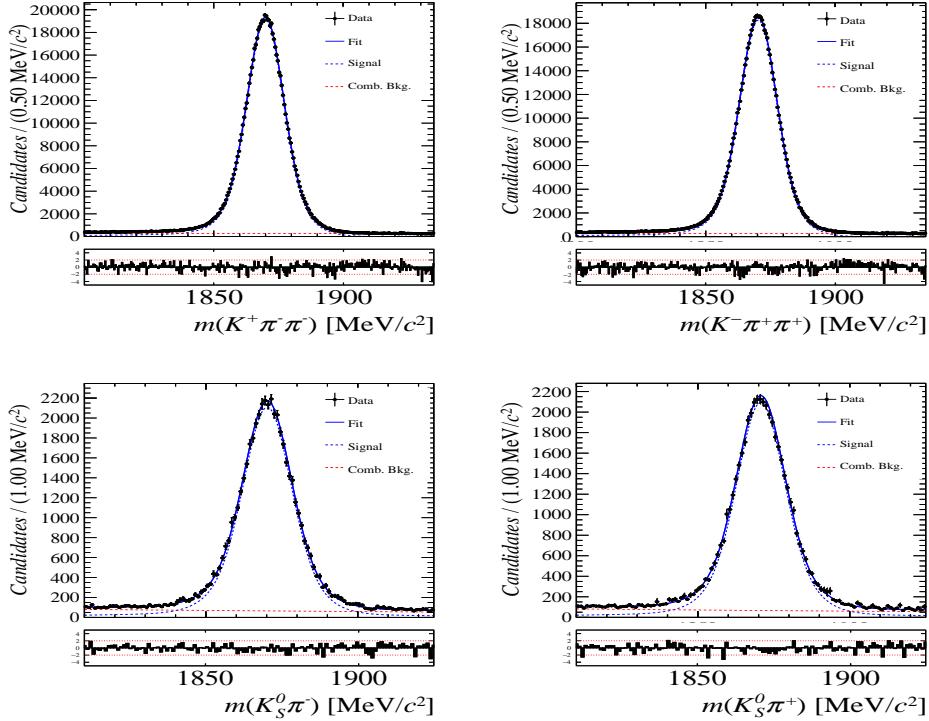

Figure 8.2: Distributions of the invariant mass of (top) $D^\pm \rightarrow K^\pm \pi^\pm \pi^\pm$ and (bottom) $D^\pm \rightarrow K_s^0 \pi^\pm$ candidates for Run-II data from the calibration samples. A fit described in the text is overlaid.

Data sample	$A^{det}(K^-\pi^+) + A(K^0)$ [%]
Run-I	
2011, mag. up	-2.01 \pm 0.32
2011, mag. down	-0.16 \pm 0.28
2011, average	-1.09 \pm 0.21
2012, mag. up	-0.90 \pm 0.20
2012, mag. down	-1.01 \pm 0.22
2012, average	-0.96 \pm 0.15
Run-II

average	-0.91 \pm 0.22

Table 8.2: Summary of the $K^-\pi^+$ detection asymmetry obtained from the fits to the Run-I and Run-II calibration samples.

768 9 Decay-time fit

769 This section covers the (phase space integrated) decay-time fits to $B_s^0 \rightarrow D_s h\pi\pi$ data. We
 770 use the **sFit** technique [46] to statistically subtract the background, leaving only the signal
 771 PDF to describe the decay-time. The **sWeights** are calculated based on the fit to the
 772 reconstructed B_s mass distribution described in Sec. 4. The signal PDF is conditional on
 773 the tagging decisions q_i , the mistag estimates η_i ($i = \text{OS,SS}$) and the decay-time error δt :

$$\mathcal{P}(t|\delta t, q_{\text{OS}}, \eta_{\text{OS}}, q_{\text{SS}}, \eta_{\text{SS}}) \propto \left[p(t' | q_{\text{OS}}, \eta_{\text{OS}}, q_{\text{SS}}, \eta_{\text{SS}}) \otimes \mathcal{R}(t - t', \delta t) \right] \cdot \epsilon(t) \quad (9.1)$$

774 where $p(t|q_{\text{OS}}, \eta_{\text{OS}}, q_{\text{SS}}, \eta_{\text{SS}})$ is given by Equation 2.7 taking the tagging dilution into
 775 account. The decay-time acceptance $\epsilon(t)$ (Sec. 6) and the Gaussian time-resolution
 776 function $\mathcal{R}(t - t', \delta t)$ (Sec. 5) are fixed to the values obtained by the dedicated studies.
 777 We fix the values of Γ_s and $\Delta\Gamma_s$ to the latest HFLAV results [38].

778 The unbinned maximum likelihood fits are performed simultaneously in six categories:
 779 [Run-I,L0-TOS], [Run-I,L0-TIS], [Year-15/16,L0-TOS], [Year-15/16,L0-TIS], [Year-17,L0-
 780 TOS] and [Year-17,L0-TIS] to account for different time-acceptance shapes, time-resolution
 781 and tagging calibrations.

782 9.1 Fit to $B_s^0 \rightarrow D_s \pi\pi\pi$ data

783 Since the decay $B_s^0 \rightarrow D_s \pi\pi\pi$ is flavour specific, the CP coefficients can be fixed to $C = 1$
 784 and $D_f = D_{\bar{f}} = S_f = S_{\bar{f}} = 0$. The fit determines the calibration parameters for the
 785 OS-Combo and SS-Kaon taggers, the B_s^0 production asymmetry for Run-II data as well as
 786 the mixing frequency Δm_s . Table 9.1 summarizes the fitted parameters. The **sWeighted**
 787 decay-time distribution and the time-dependent asymmetry A_{mix} between mixed and
 788 unmixed B_s^0 candidates are shown in Fig. 9.1 along with the fit projections.

789 9.2 Fit to $B_s^0 \rightarrow D_s K\pi\pi$ data

790 The measured CP coefficients $C, D_f, D_{\bar{f}}, S_f$ and $S_{\bar{f}}$ extracted from a fit to the
 791 $B_s \rightarrow D_s K\pi\pi$ decay-time distribution are reported in Table 9.2. The fit projection is
 792 shown in Fig. 9.2. We included a multi-dimensional Gaussian-constraint for the tagging
 793 calibration parameters (including the tagging asymmetries) with the central values and
 794 covariance matrix determined in Sec. 9.1.

795

796

The CP coefficients will be converted to the observables $r, \kappa, \delta, \gamma$ using the Gamma-
 797 Combo package after unblinding.

798

Currently the mixing frequency is fixed to the HFLAV value. We intend to update
 799 the fit after unblinding our result from the $B_s^0 \rightarrow D_s \pi\pi\pi$ fit since our precision is
 significantly higher.

Table 9.1: Parameters determined from a fit to the $B_s \rightarrow D_s \pi\pi\pi$ decay-time distribution. The uncertainties are statistical and systematic, respectively.

Fit Parameter	Run-I	Run-II

799 10 Time-dependent amplitude fit

800 The signal PDF used for the full time-dependent fit is defined as

$$\mathcal{P}(\mathbf{x}, t | \delta t, q_{OS}, \eta_{OS}, q_{SS}, \eta_{SS}) \propto \left[p(\mathbf{x}, t' | q_{OS}, \eta_{OS}, q_{SS}, \eta_{SS}) \otimes \mathcal{R}(t - t', \delta t) \right] \cdot \epsilon(t) \quad (10.1)$$

801 where $p(\mathbf{x}, t | q_{OS}, \eta_{OS}, q_{SS}, \eta_{SS})$ is given the differential decay rate in Equation 2.29 taking
 802 the tagging dilution into account. The phase space efficiency $\epsilon(\mathbf{x})$ is only included in the
 803 normalization of $\mathcal{P}(\mathbf{x}, t | \delta t, q_{OS}, \eta_{OS}, q_{SS}, \eta_{SS})$ as discussed in Sec 6.3. The model selection
 804 of the amplitude components is described in the following Section. The remaining fitting
 805 strategy is exactly the same as for the decay-time fits, see Sec. 9.

806 10.1 Signal Model Construction

807 The light meson spectrum comprises multiple resonances which are expected to contribute
 808 to $B_s \rightarrow D_s K\pi\pi$ decays as intermediate states. Apart from clear contributions coming
 809 from resonances such as $K_1(1270)$, $K_1(1400)$, $\rho(770)$ and $K^*(892)^0$, the remaining structure
 810 is impossible to infer due to the cornucopia of broad, overlapping and interfering resonances
 811 within the phase space boundary. We follow the LASSO [47, 48] approach to limit the
 812 model complexity in two steps.

813 First, we fit the time-integrated and flavour averaged phase-space distribution of
 814 $B_s \rightarrow D_s K\pi\pi$ decays. In this case, a single total amplitude can be used:

$$\mathcal{A}_f^{eff}(\mathbf{x}) = \sum_i a_i^{eff} A_i(\mathbf{x}) \quad (10.2)$$

815 which effectively describes the incoherent superposition of the $b \rightarrow c$ and $b \rightarrow u$ amplitudes:

$$|A_f^{eff}(\mathbf{x})|^2 = |A_f^c(\mathbf{x})|^2 + |A_f^u(\mathbf{x})|^2. \quad (10.3)$$

816 This significantly simplifies the fitting procedure and allows us to include the whole pool
 817 of considered intermediate state amplitudes A_i which can be found in Appendix I. The
 818 LASSO penalty term added to the likelihood function

$$-2 \log \mathcal{L} \rightarrow -2 \log \mathcal{L} + \lambda \sum_i \sqrt{\int |a_i^{eff} A_i(\mathbf{x})|^2 d\Phi_4}, \quad (10.4)$$

819 shrinks the amplitude coefficients towards zero. The amount of shrinkage is controlled by
 820 the parameter λ , to be tuned on data. Higher values for λ encourage sparse models, *i.e.*
 821 models with only a few non-zero amplitude coefficients. The optimal value for λ is found
 822 by minimizing the Bayesian information criteria [49] (BIC),

$$BIC(\lambda) = -2 \log \mathcal{L} + r \log N_{Sig}, \quad (10.5)$$

823 where N_{Sig} is the number of signal events and r is the number of amplitudes with a decay
 824 fraction above a certain threshold. The fit fractions are defined as

$$F_i \equiv \frac{\int |a_i^{eff} A_i(\mathbf{x})|^2 d\Phi_4}{\int |\mathcal{A}_f^{eff}(\mathbf{x})|^2 d\Phi_4}, \quad (10.6)$$

and are a measure of the relative strength between the different transitions. Figure 10.1(left) shows the distribution of BIC values obtained by scanning over λ where we choose the decay fraction threshold to be 0.5%. At the optimal value of $\lambda = 50$, the set of amplitudes with a decay fraction above the threshold are considered further for step two of the model selection. The selected amplitudes and their fractions are summarized in Table 10.1. The fit projections are shown in Fig. 10.2. The set of selected amplitudes is stable for thresholds between 0.1% and 1%.. Other choices result in marginally different models containing one component more or less. These are included in the set of alternative models used for the systematic studies presented in Sec. 11.10.

In Stage 2, the LASSO procedure is again performed by fitting the full time-dependent amplitude PDF. The components selected by Stage 1 are included for both $b \rightarrow c$ and $b \rightarrow u$ transitions and the likelihood is extended as follows:

$$-2 \log \mathcal{L} \rightarrow -2 \log \mathcal{L} + \lambda \sum_i \sqrt{\int |a_i^c A_i(\mathbf{x})|^2 d\Phi_4} + \lambda \sum_i \sqrt{\int |a_i^u A_i(\mathbf{x})|^2 d\Phi_4} \quad (10.7)$$

Figure 10.1(right) shows a plot of the complexity factor λ , against the resulting BIC values. The final set of $b \rightarrow c$ and $b \rightarrow u$ amplitudes is selected using the optimal value of $\lambda = 28$, and is henceforth called the LASSO model.

Table 10.1: Fit fractions of the amplitudes selected by Stage 1 of the model selection procedure.

Decay channel	Fraction [%]
$B_s \rightarrow K(1)(1270)^+ (\rightarrow K^*(892)^0 (\rightarrow K^+ \pi^-) \pi^+) D_s^-$	8.56 ± 1.43
$B_s \rightarrow K(1)(1400)^+ (\rightarrow K^*(892)^0 (\rightarrow K^+ \pi^-) \pi^+) D_s^-$	43.72 ± 2.80
$B_s \rightarrow K(1460)^+ (\rightarrow K^*(892)^0 (\rightarrow K^+ \pi^-) \pi^+) D_s^-$	3.25 ± 0.69
$B_s \rightarrow K^*(1410)^+ (\rightarrow K^*(892)^0 (\rightarrow K^+ \pi^-) \pi^+) D_s^-$	15.33 ± 1.13
$B_s \rightarrow (D_s^- \pi^+) P K^*(892)^0 (\rightarrow K^+ \pi^-)$	4.63 ± 0.69
$B_s \rightarrow K^*(1410)^+ (\rightarrow \rho(770)^0 (\rightarrow \pi^+ \pi^-) K^+) D_s^-$	5.58 ± 0.62
$B_s \rightarrow (D_s^- K^+) P \rho(770)^0 (\rightarrow \pi^+ \pi^-)$	1.49 ± 0.40
$B_s \rightarrow K(1)(1270)^+ (\rightarrow K(0)^*(1430)^0 (\rightarrow K^+ \pi^-) \pi^+) D_s^-$	4.72 ± 0.54
$B_s \rightarrow K(1)(1270)^+ (\rightarrow \rho(770)^0 (\rightarrow \pi^+ \pi^-) K^+) D_s^-$	14.20 ± 1.56
Sum	101.47 ± 3.86

840 10.2 Results

841 Table 10.2 lists the modulus and phases of the complex amplitude coefficients a_i^c and a_i^u ,
 842 obtained by fitting the LASSO model to the data. The corresponding fit fractions for the
 843 $b \rightarrow c$ and $b \rightarrow u$ amplitudes are individually normalized

$$F_i^{c,u} \equiv \frac{\int |a_i^{c,u} A_i(\mathbf{x})|^2 d\Phi_4}{\int |\mathcal{A}_f^{c,u}(\mathbf{x})|^2 d\Phi_4} \quad (10.8)$$

844 and shown in Table 10.3. In addition to the amplitude coefficients, the amplitude ratio
 845 and the strong and weak phase differences between the $b \rightarrow c$ and $b \rightarrow u$ decays are
 846 determined. Moreover, the masses and widths of the $K_1(1400)$ and $K^*(1410)$ resonances
 847 are fitted.

848 Figure 10.4 shows the distributions of selected phase space observables, which demon-
 849 strate reasonable agreement between data and the fit model. We also project into the
 850 transversity basis to demonstrate good description of the overall angular structure (see
 851 10.4 bottom row). The acoplanarity angle χ , is the angle between the two decay planes
 852 formed by the $K^+\pi^-$ system and the $D_s^-\pi^+$ system in the B_s rest frame; boosting into the
 853 rest frames of the two-body systems defining these decay planes, the two helicity variables
 854 are defined as the cosine of the angle, θ , of the K^+ or D_s^- momentum with the B_s flight
 855 direction.

856 In order to quantify the quality of the fit in the five-dimensional phase space, a χ^2
 857 value is determined by binning the data;

$$\chi^2 = \sum_{b=1}^{N_{\text{bins}}} \frac{(N_b - N_b^{\text{exp}})^2}{N_b^{\text{exp}}}, \quad (10.9)$$

858 where N_b is the number of data events in a given bin, N_b^{exp} is the event count predicted
 859 by the fitted PDF and N_{bins} is the number of bins. An adaptive binning is used to ensure
 860 sufficient statistics in each bin for a robust χ^2 calculation [50]. At least 25 events per
 861 bin are required. The number of degrees of freedom ν , in an unbinned fit is bounded by
 862 $N_{\text{bins}} - 1$ and $(N_{\text{bins}} - 1) - N_{\text{par}}$, where N_{par} is the number of free fit parameters. We use
 863 the χ^2 value divided by $\nu = (N_{\text{bins}} - 1) - N_{\text{par}}$ as a conservative estimate. For the LASSO
 864 model, this amounts to $\chi^2/\nu = 1.40$ with $\nu = 137$, indicating a decent fit quality.

Table 10.2: Modulus and phases of the amplitudes contributing to $b \rightarrow c$ and $b \rightarrow u$ decays. In case of multiple decay modes of three-body resonances, the amplitude coefficients are defined relative to the one listed first. Additional fit parameters are listed below. The first quoted uncertainty is statistical, while the second arises from systematic sources. The third uncertainty arises from the alternative models considered.

865 11 Systematic uncertainties

866 The systematic uncertainties on the measured observables are summarized in Table 11.3 for
867 the decay-time fit to $B_s \rightarrow D_s \pi\pi\pi$, in Table 11.4 for the decay-time fit to $B_s \rightarrow D_s K\pi\pi$
868 and in Table 11.5 for the full time-dependent amplitude fit to $B_s \rightarrow D_s K\pi\pi$ decays. A
869 description of each systematic effect is given in the following subsections starting with the
870 ones common to all fits. Afterwards, systematic effect specific to the amplitude description
871 are discussed.

872 11.1 Fit bias

873 Pseudo-experiments are performed, where a signal toy sample of the same size as the
874 number of observed signal data events is generated according to the nominal fit model
875 and subsequently fitted with the same model. The means of the pull distributions are
876 taken as systematic uncertainties of the fit parameters.

877 11.2 Background subtraction

878 The statistical subtraction of the residual background [46], left after the full selection,
879 relies on the correct description of the invariant B_s^0 mass distribution. Since the choice of
880 signal and background models is not unique, alternative parameterizations are tested:

- 881 • The Johnson's SU function which is used as nominal signal model is replaced by the
882 sum of two Crystal Ball functions [51].
- 883 • For the combinatorial background, the nominal second order polynomial is replaced
884 by an exponential function.
- 885 • For the description of the partially reconstructed background, a combination of the
886 RooHILLdini and RooHORNsdini model [52] is used instead of the nominal model of
887 three bifurcated gaussians.
- 888 • For the shape of the mis-ID background, the nominal approach is to use a simulated
889 sample of $B_s^0 \rightarrow D_s^- \pi^+ \pi^- \pi^+$ or $B_s^0 \rightarrow D_s^{*-} \pi^+ \pi^- \pi^+$ decays and flip the mass
890 hypothesis of the π^+ with the higher misidentification probability (see Sec. 4).
891 Two alternative approaches are considered: we flip the mass hypothesis of the π^+
892 candidate with the lower probability of being misidentified; we randomly flip the
893 mass hypothesis of a π^+ candidate. To account for the systematic of the $\pi \rightarrow K$
894 fake rate, we vary the default PIDK cut ($\text{PIDK} > 10$) by ± 2 when calculating the
895 misID weights from `PIDCalib`.

896 In total 10 (7) different combinations of the modifications discussed above are tested
897 for the fit to the $D_s K\pi\pi$ ($D_s \pi\pi\pi$) mass distribution. For each case, new signal `sWeights`
898 are calculated and the `sFits` to data are repeated. The sample variance of the obtained
899 differences to the nominal fit value are used as systematic uncertainty due to the background
900 subtraction.

901 11.3 Decay-time acceptance

902 The systematic uncertainty related to the decay-time efficiency as well as Γ_s and $\Delta\Gamma_s$ are
 903 studied simultaneously. We generate toys in the nominal configuration and fit back in
 904 both this nominal configuration and a configuration in which we have randomized the
 905 acceptance parameters together with Γ_s and $\Delta\Gamma_s$ within their uncertainties. For each toy,
 906 a pull is calculated by dividing the difference between the fitted values of the nominal
 907 and shifted configurations by the uncertainty in the nominal toy. We add the bias in the
 908 mean of this pull to its width, in quadrature, in order to arrive at the final systematic
 909 uncertainty.

910 To improve the coverage of the multi-dimensional parameter space, a Cholesky decom-
 911 position [53] is used to generate a set of uncorrelated vectors from the covariance matrix
 912 $\text{cov}(\lambda_i, \lambda_j)$, where the vector λ includes the parameters Γ_s , $\Delta\Gamma_s$ and the $N = 4$ spline
 913 coefficients for each category of the simultaneous fit. The correlations between Γ_s ($\Delta\Gamma_s$)
 914 and the spline coefficients are measured by rerunning the acceptance fits described in
 915 Sec. 6.2 with the values of Γ_s ($\Delta\Gamma_s$) varied by $\pm 1\sigma$ and measuring the shift in the spline
 916 coefficients as a fraction of their uncertainty. For the correlation between Γ_s and $\Delta\Gamma_s$ we
 917 use the HFLAV value [38].

918 11.4 Decay-time resolution and tagging

919 To study systematic effects originating from the scaling of the decay-time error estimate,
 920 two different approaches which either slightly overestimate or underestimate the resolution
 921 are used:

- 922 • A double Gaussian is fit to the decay-time distributions of fake B_s^0 candidates, but
 923 only the width of the core Gaussian is considered to represent the time resolution in
 924 the respective bin. Therefore the resolution is slightly underestimated in this case.
- 925 • A single Gaussian is fit to the decay-time distributions of fake B_s^0 candidates in a
 926 wide range of $[-3\sigma_t : 1.5\sigma_t]$. Due to the tails of the distribution, which broaden the
 927 width of the Gaussian function, this method slightly overestimates the decay-time
 928 resolution.

929 For each case, a new scaling function is derived:

$$\sigma_{\text{eff},\text{Data},16}^{\text{core-Gauss}}(\sigma_t) = (6.8 \pm 1.9) \text{ fs} + (0.797 \pm 0.050) \sigma_t \quad (11.1)$$

$$\sigma_{\text{effData},16}^{\text{single-Gauss}}(\sigma_t) = (10.1 \pm 1.5) \text{ fs} + (0.950 \pm 0.039) \sigma_t \quad (11.2)$$

$$\sigma_{\text{eff},\text{Data},17}^{\text{core-Gauss}}(\sigma_t) = (0.1 \pm 1.5) \text{ fs} + (0.957 \pm 0.037) \sigma_t \quad (11.3)$$

$$\sigma_{\text{effData},17}^{\text{single-Gauss}}(\sigma_t) = (5.6 \pm 1.2) \text{ fs} + (1.012 \pm 0.031) \sigma_t \quad (11.4)$$

933 They are compared to the nominal result in Fig. 11.1.

934 Due to the high correlation between the decay-time resolution and the tagging calibra-
 935 tion, their systematic uncertainty has to be studied simultaneously. First, the decay-time
 936 fits to $B_s \rightarrow D_s \pi\pi\pi$ data are repeated using the alternative decay-time error scaling
 937 functions. New tagging calibration parameters are obtained which are then used (together
 938 with the respective decay-time error scaling function) in the fits to $B_s \rightarrow D_s K\pi\pi$ data

to define the Gaussian-constraints as discussed in Sec. 9. For the width of the Gaussians only the statistical error of the tagging calibration parameters are used since systematic uncertainties (except the systematic arising from the decay-time resolution which is already included by the procedure described above) are found to be negligible, see Table 11.3. Finally, we take the biggest change in fit central value as the systematic for each parameter of the $B_s \rightarrow D_s K\pi\pi$ fits.

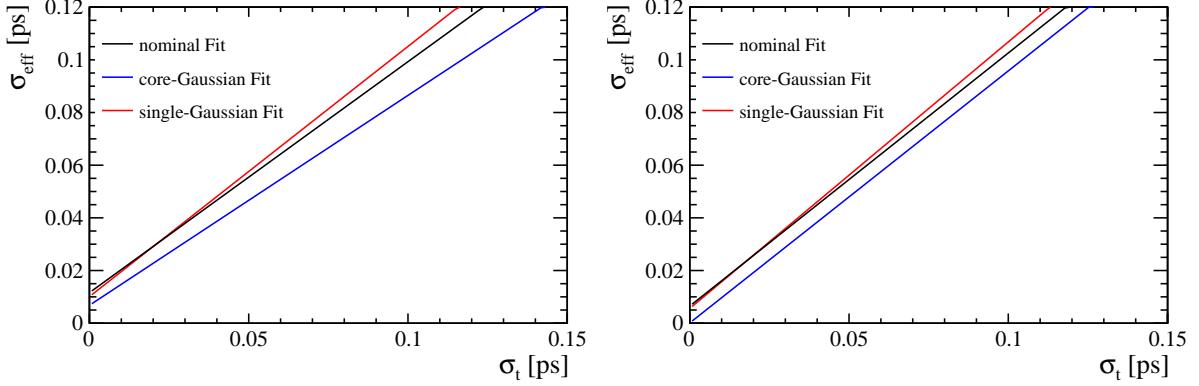

Figure 11.1: The measured resolution scaling function of the per-event decay time error estimate σ_t for fake B_s candidates (Run-II data) for (black line) the nominal scaling, (blue line) only using the narrow gaussian width of the double gaussian fit model or (red line) when determining the resolution using a single gaussian model. Data taken in (left) 2016 and (right) 2017.

11.5 Production, detection asymmetries and mixing frequency

The systematic from the production, detection asymmetries and Δm_s (in case of $B_s \rightarrow D_s K\pi\pi$ decays) which are fixed in the fit are evaluated by means of a toy study similar to the procedure performed for the time-acceptance. The parameters are assumed to be uncorrelated.

11.6 Multiple candidates

The fraction of events with multiple candidates has been found to be very small, it is 1.6% for $D_s K\pi\pi$ and 1.5% for $D_s \pi\pi\pi$. Thus the nominal result is obtained keeping all candidates, while a systematic uncertainty is assigned by repeating the fit randomly keeping only one candidate when multiple ones are founds. No shifts in the fit central values are observed.

11.7 Length and momentum scales

The uncertainty on the LHCb length scale is estimated to be at most 0.020% [54], which translates directly in an uncertainty on Δm_s of 0.020% with other parameters being unaffected. The momentum scale uncertainty is at most 0.022%.

960 **11.8 Phase space acceptance**

961 For the phase space acceptance we rely on simulated data. The integration error due to
962 the limited size of the MC sample used to normalize the signal PDF is below 0.2% and
963 thus negligible small.

964 To asses the uncertainty due to possible data-simulation differences, we determine
965 alternative phase space efficiencies by varying the selection requirements on quantities
966 that are expected not to be well described by the simulation. In particular, we consider
967 the following variations:

- 968 • No BDT cut is applied
- 969 • A tighter BDT requirement is used ($\text{BDTG} > 0.6$)
- 970 • No reweighting is applied
- 971 • Instead of the PID responses obtained from the `PIDCorr` tool, we use the `PIDGen`
972 tool to resample the PID variables [37]
- 973 • The raw MC PID variables are used
- 974 • Candidates with `BKGCAT= 60` are removed

975 We assign the sample variance of the fitted values using the alternative phase space
976 acceptances as systematic.

977 **11.9 Resonance description**

978 The following alternative line shape parameterizations are considered as part of the
979 systematic studies:

- 980 • The Lass description for the $K\pi$ S -wave is replaced by a more general model
981 (Glass [55, 56])
- 982 • The Gounaris-Sakurai description for the $\rho(770)$ is replaced by a relativistic Breit-
983 Wigner propagator (Equation 2.16)
- 984 • The ω contribution to the decay channel $K_1(1270) \rightarrow K \rho(770)/\omega$ is set to zero
- 985 • For the decay channel $K^*(1410) \rightarrow K \rho(770)$, we include $\rho(770) - \omega$ mixing with a
986 relative magnitude and phase determined from data
- 987 • Instead of taking the energy-dependent widths of the three-body resonances from
988 Refs. [9, 21], we derive them from Equation 2.17 taking only the dominant $K\pi\pi$
989 decay mode into account

990 The data fits are repeated for each alternative model and the RMS of the central values
991 are taken as systematic uncertainties.

992 The uncertainties due to fixed masses and widths of resonances are evaluated from
993 toys where we vary them one-by-one within their quoted errors. In our nominal fit, the
994 Blatt-Weisskopf radial parameter is set to $r_{BW} = 1.5 \text{ GeV}^{-1}$. Again, toys are generated
995 according to this nominal configuration and then fitted whereby the radial parameter is
996 uniformly varied within the interval $[0, 3] \text{ GeV}^{-1}$.

997 11.10 Alternative amplitude models

998 We tested several modifications of the LASSO model to assign an additional model
999 uncertainty to the measured observables r, δ and $\gamma - 2\beta_s$ as well as to the measured
1000 masses and widths of the $K_1(1400)$ and $K^*(1410)$ resonances. The amplitude coefficients
1001 are by definition parameters of a given model which is why we do not evaluate a model
1002 uncertainty for them. The fit results of the following alternative models (Alt. 1 - Alt. 12)
1003 are summarized in Tables 11.1 and 11.2.

- 1004 • All amplitudes selected by Stage 1 of the model selection are included for both $b \rightarrow c$ and
1005 $b \rightarrow u$ transitions (Alt. 1)
- 1006 • The decay channel $K_1(1270)[D] \rightarrow K^*(892)\pi$, where the $K^*(892)\pi$ system is in relative a
1007 D-wave state, is added (Alt. 2)
- 1008 • The decay channel $K_1(1400) \rightarrow K\rho(770)$ is added (Alt. 12)
- 1009 • The decay channels $K(1460) \rightarrow K\rho(770)$ and $K(1460) \rightarrow K\sigma$ are added (Alt. 3)
- 1010 • The decay channels $K^*(1680) \rightarrow K\rho(770)$ and $K^*(1680) \rightarrow K^*(892)\pi$ are added (Alt. 9)
- 1011 • The decay channel $K_2(1770) \rightarrow K^*(892)\pi$ is added (Alt. 10)
- 1012 • The amplitude $B_s \rightarrow (D_s K)_P \rho(770)$ is replaced by $B_s \rightarrow (D_s K)_S \rho(770)$ (Alt. 11)
- 1013 • Higher orbital angular momentum states are added for the amplitudes: $B_s \rightarrow$
1014 $(D_s \pi)_P K^*(892)$ and $B_s \rightarrow (D_s K)_P \rho(770)$ (Alt. 4 and Alt. 5)
- 1015 • The amplitudes $B_s \rightarrow (D_s K)\sigma$, $B_s \rightarrow (D_s K)f_0(980)$, $B_s \rightarrow (D_s K)f_2(1270)$ and
1016 $B_s \rightarrow (D_s K)f_0(1370)$ are added in different combinations and angular momentum
1017 configurations (Alt. 6, Alt. 7 and Alt. 8)
- 1018 • The decay channels $K_2^*(1430) \rightarrow K\rho(770)$ and $K_2^*(1430) \rightarrow K^*(892)\pi$ are added (not
1019 used)
- 1020 • The amplitudes $B_s \rightarrow (D_s \pi)_P K_0^*(1430)$ and $B_s \rightarrow (D_s K)_S K_2^*(1430)$ are added (not
1021 used)
- 1022 • A flat non-resonant $B_s \rightarrow D_s K \pi\pi$ component is added (not used)

1023 In total 15 different sets of amplitudes are fitted. In some cases, the fit fractions of
1024 additionally added amplitudes turn out to be exactly zero. These model are effectively
1025 not distinguishable from the baseline LASSO model and are not considered further. From
1026 the remaining 12 models, we compute the sample variance for each observable and take it
1027 as model uncertainty.

Table 11.1: Fit fractions in percent for the baseline and several alternative amplitude models (Alt. 1 - Alt. 6). Resonance parameters and the physical observables $r, \kappa, \delta, \gamma - 2\beta_s$ are also given. The values of the physical observables are given relative to the baseline result. The uncertainties are statistical only.

	Baseline	Alt.1	Alt.2	Alt.3	Alt.4	Alt.5	Alt.6

1028 12 Summary

1029 The B_s^0 oscillation frequency Δm_s is measured from the time-dependent fit to $B_s^0 \rightarrow D_s\pi\pi\pi$
 1030 data to be

$$\Delta m_s = xx.xxx \pm 0.009 \pm 0.006,$$

1031 where the errors are statistical and systematic, respectively.

1032 Table 12.1 summarizes the values for the ratio of the $b \rightarrow u$ and $b \rightarrow c$ transition
 1033 amplitudes (r) and their strong (δ) and weak phase ($\gamma - 2\beta_s$) difference obtained from
 1034 the phase-space integrated, as well as the time-dependent amplitude fit to $B_s^0 \rightarrow D_s K\pi\pi$
 1035 data.

Table 12.1: Parameters determined from the two fits performed to the $B_s^0 \rightarrow D_s K\pi\pi$ decay-time distribution. The uncertainties on the amplitude fit are statistical, systematic and due to the amplitude model, respectively, while for the phase-space integrated fit, systematic and statistical uncertainties are combined.

Parameter	Phase-space integrated fit	Time-dependent amplitude fit
r	$xx.xx \pm xx.xx$	$xx.xx \pm 0.03 \pm 0.03 \pm 0.02$
δ [°]	$xx.xx \pm xx.xx$	$xx.xx \pm 15.0 \pm 6.0 \pm 7.8$
$\gamma - 2\beta_s$ [°]	$xx.xx \pm xx.xx$	$xx.xx \pm 16.4 \pm 6.1 \pm 6.5$

1036 Furthermore, the masses and widths of the $K_1(1400)$ and the $K^*(1410)$ resonances are
 1037 measured in the time-dependent amplitude fit:

$$m_{K_1(1400)} [\text{MeV}/c^2] = 1398 \pm 9 \pm 4 \pm 6, \\ \Gamma_{K_1(1400)} [\text{MeV}/c^2] = 204 \pm 14 \pm 9 \pm 9, \\ m_{K^*(1410)} [\text{MeV}/c^2] = 1432 \pm 12 \pm 15 \pm 8, \\ m_{K^*(1410)} [\text{MeV}/c^2] = 344 \pm 25 \pm 35 \pm 18,$$

1038 where the uncertainties are statistical, systematic and due to the choice of amplitude
 1039 models, respectively.

1040 A Stripping and Trigger cuts

1041 The following text describes variables which are used in Table A.1 and might be ambiguous,
 1042 or which benefits are not straight forward. Where noted, different cut values are applied
 1043 for Run-I and Run-II data. In Table A.1, DOCA is the abbreviation for distance of closest
 1044 approach. This variable is used to ensure that all D_s and $X_{s,d}$ daughters originate from
 1045 the same vertex. DIRA is the abbreviation for the cosine of the angle θ between the
 hadron's flight direction \vec{x} and it's corresponding momentum vector \vec{p} , $\cos \theta_{\vec{x}-\vec{p}}$.

Table A.1: Summary of the stripping selections for $B_s^0 \rightarrow D_s K \pi \pi$ decays. The requirements for Run-II are only given if they have been changed.

Variable	Stripping Cut (Run-I)	Stripping Cut (Run-II)
Track χ^2/nDoF	< 3	
Track p	> 1000 MeV/ c	
Track p_T	> 100 MeV/ c	
Track IP χ^2	> 4	
Track ghost-prob.	< 0.4	
D_s mass	$m_{D_s} \pm 100$ MeV	$m_{D_s} \pm 80$ MeV
D_s Daughter p_T	$\sum_{i=1}^3 p_{t,i} > 1800$ MeV/ c	
D_s Daughter DOCA	< 0.5 mm	
D_s Vertex χ^2/nDoF	< 10	
D_s χ^2 -separation from PV	> 36	
D_s daughter PID(π)	< 20	
D_s daughter PID(K)	> -10	
$X_{s,d}$ mass	< 4000 MeV	< 3500 MeV
$X_{s,d}$ Daughter p	> 2 GeV/ c	
$X_{s,d}$ Daughter DOCA	< 0.4 mm	
$X_{s,d}$ Daughter p_T	$\sum_{i=1}^3 p_{t,i} > 1250$ MeV/ c	
$X_{s,d}$ Vertex χ^2/nDoF	< 8	
$X_{s,d}$ χ^2 -separation from PV	> 16	
$X_{s,d}$ DIRA	> 0.98	
$X_{s,d}$ $\Delta\rho$	> 0.1 mm	
$X_{s,d}$ Δz	> 2.0 mm	
$X_{s,d}$ daughter PID(π)	< 10	
X_s daughter PID(K)	> -2	> 4
B_s^0 mass	[4750, 7000] MeV/ c^2	[5000, 6000] MeV/ c^2
B_s^0 DIRA	> 0.98	> 0.99994
B_s^0 min IP χ^2	< 25	< 20
B_s^0 Vertex χ^2/nDoF	< 10	< 8
$B_s^0 \tau_{B_s^0}$	> 0.2 ps	

1047 Table A.2 summarizes the trigger requirements imposed by the Hlt1 line used in this
1048 analysis for Run-I. At least one of the six decay particles must pass the listed requirements
1049 in order for the event to be stored for further analysis. For Run-II, this trigger line was
1050 updated and uses a multivariate classifier which takes the variables listed in Table A.2 as
1051 input, rather than directly cutting on them.

1052 The Hlt2 2, 3 and 4-body topological lines use a Boosted Decision Tree based on the
1053 b-hadron p_T , its flight distance χ^2 from the nearest PV and the sum of the B_s^0 and D_s
1054 vertex χ^2 divided by the sum of their number of degrees of freedom. Table A.3 summarizes
1055 the cuts applied by the inclusive ϕ trigger, which requires that a $\phi \rightarrow KK$ candidate can
be formed out of two tracks present in the event.

Table A.2: Summary of the cuts applied by the Hlt1TrackAllL0 trigger for Run-I. At least one of the six decay particles must pass this requirements, in order for the event to be accepted.

Quantity	Hlt1TrackAllL0 requirement
Track IP [mm]	> 0.1
Track IP χ^2	> 16
Track χ^2/nDoF	< 2.5
Track p_T	$> 1.7 \text{ GeV}/c$
Track p	$> 10 \text{ GeV}/c$
Number VELO hits/track	> 9
Number missed VELO hits/track	< 3
Number OT+IT $\times 2$ hits/track	> 16

Table A.3: Summary of the cuts applied by the Hlt2 inclusive ϕ trigger. A $\phi \rightarrow KK$ candidate, formed by two tracks in the event, must pass this requirements in order for the event to be accepted.

Quantity	Hlt2IncPhi requirement
ϕ mass	$m_\phi \pm 12 \text{ MeV}/c^2$ of PDG value
ϕp_T	$> 2.5 \text{ GeV}/c$
ϕ vertex χ^2/nDoF	< 20
ϕ IP χ^2 to any PV	> 5

1058 C Detailed mass fits

1059 In this section, all fits to the mass distribution of $B_s^0 \rightarrow D_s\pi\pi\pi$ and $B_s^0 \rightarrow D_sK\pi\pi$
 1060 candidates are shown. The fits are performed simultaneously in run period (Run-I, Run-
 1061 II), D_s final state ($D_s \rightarrow KK\pi$ non-resonant, $D_s \rightarrow \phi\pi$, $D_s \rightarrow K^*K$, or $D_s \rightarrow \pi\pi\pi$) and
 1062 L0 trigger category.

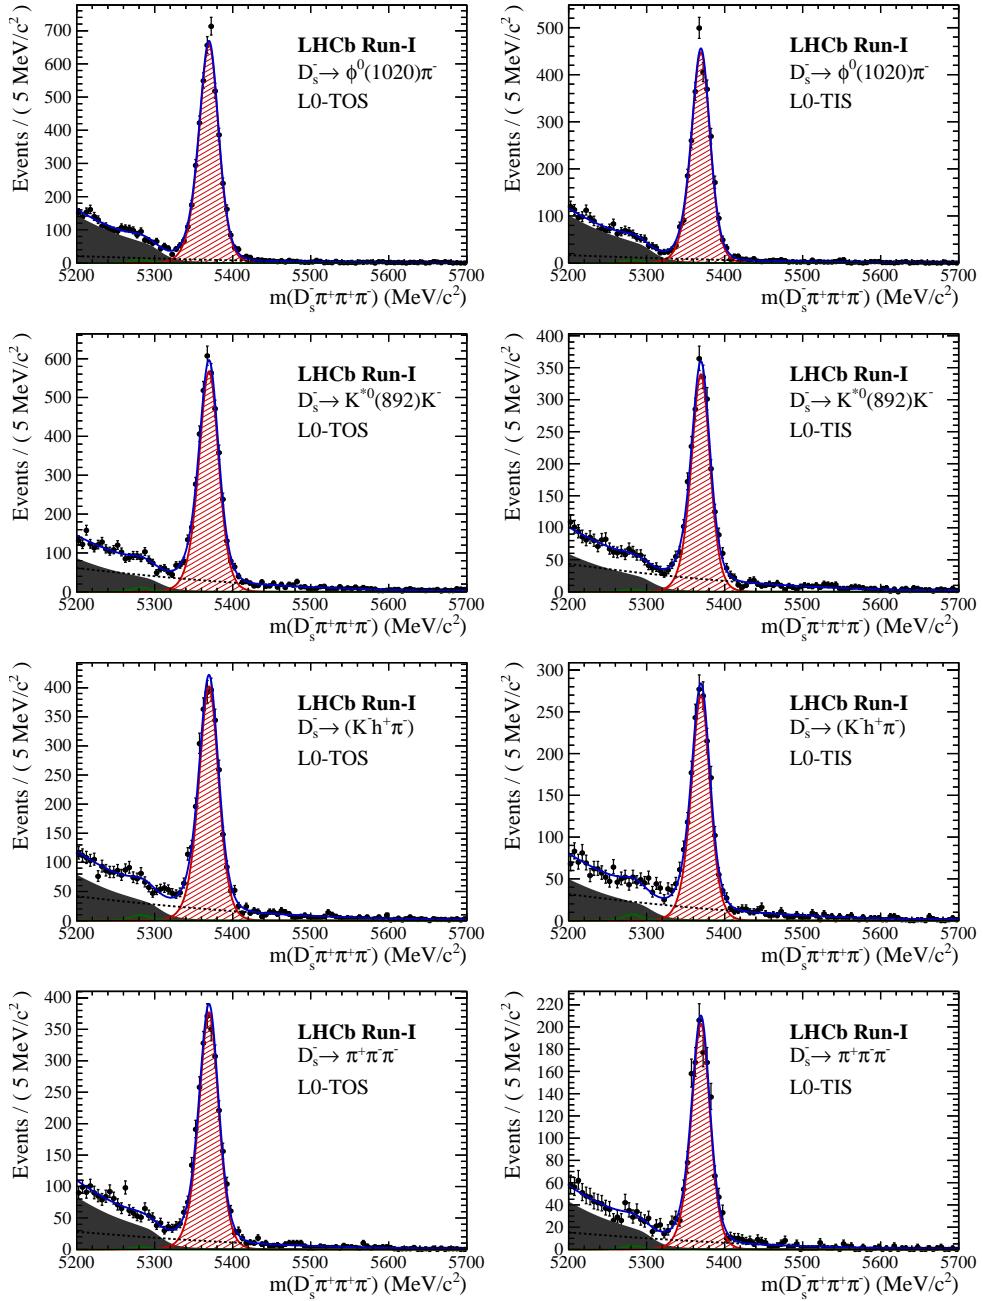

Figure C.1: Invariant mass distributions of $B_s^0 \rightarrow D_s\pi\pi\pi$ candidates for Run-I data.

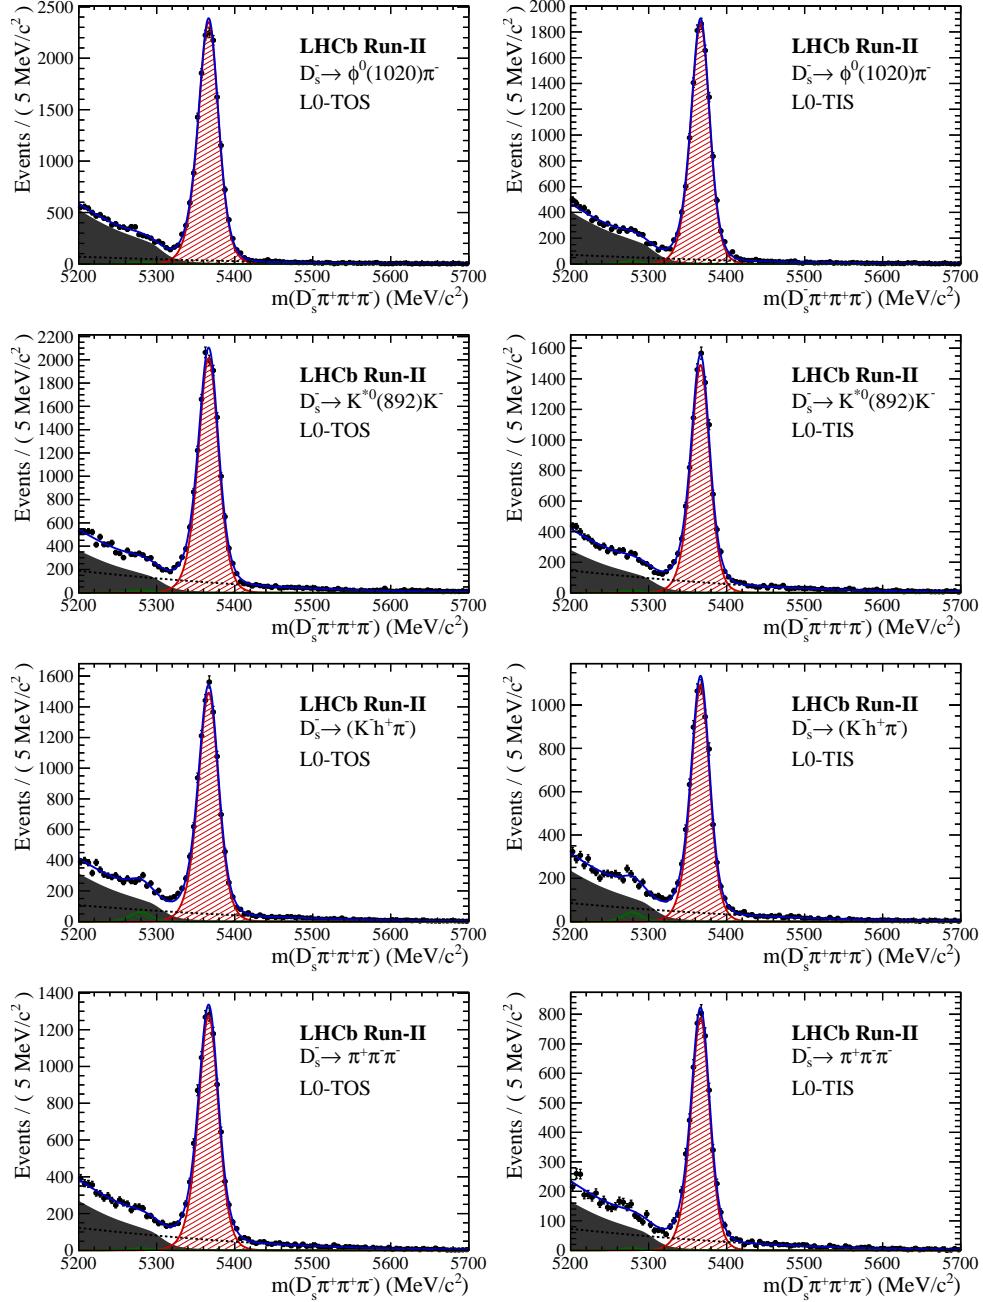

Figure C.2: Invariant mass distributions of $B_s^0 \rightarrow D_s\pi\pi\pi$ candidates for Run-II data.

Figure C.4: Invariant mass distributions of $B_s^0 \rightarrow D_s K \pi\pi$ candidates for Run-II data.

1063 D Decay-time Resolution fits

1064 This section contains all fits to the distributions of the decay time difference Δt between
 1065 the true and the reconstructed decay time of the truth-matched B_s^0 candidates on MC.
 1066 The fits are performed in bins of the decay time error σ_t , where an adaptive binning
 1067 scheme is used to ensure that approximately the same number of events are found in each
 1068 bin.

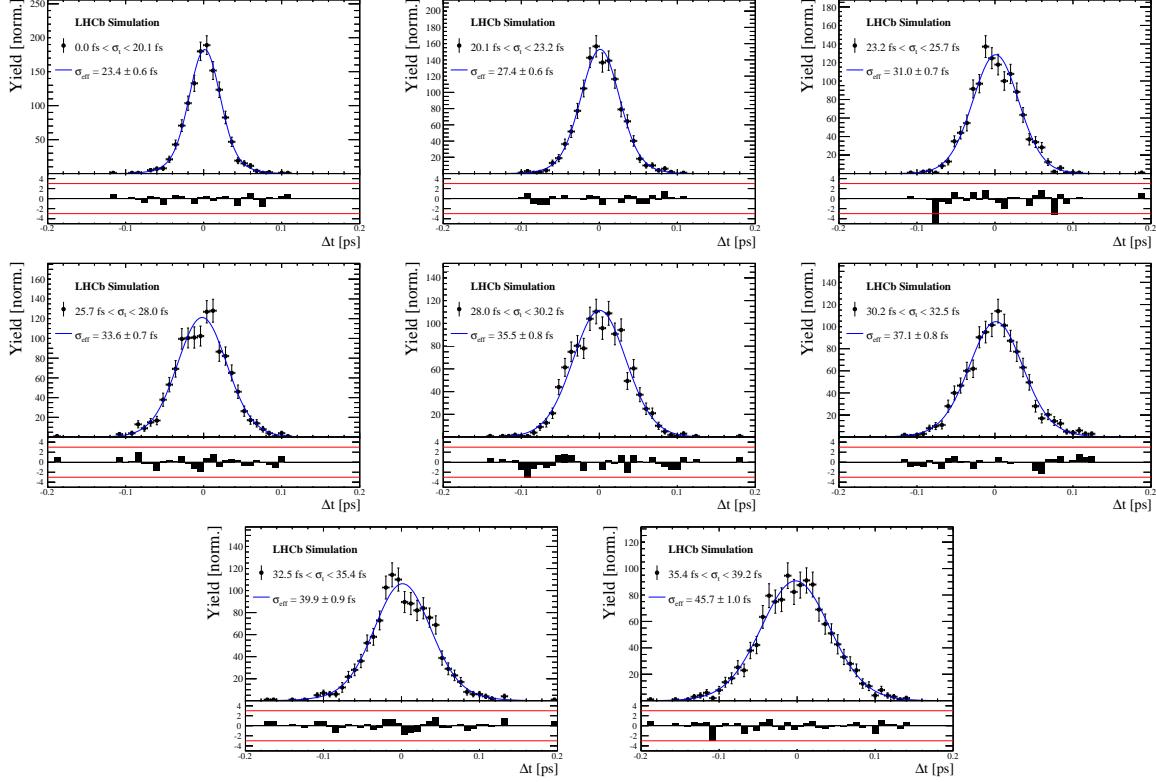

Figure D.1: Difference of the true and measured decay time of $B_s^0 \rightarrow D_s K\pi\pi$ MC candidates in bins of the per-event decay time error estimate..

Table D.1: Measured time resolution for $B_s \rightarrow D_s K\pi\pi$ MC in bins of the per-event decay time error estimate.

1069 E Comparison of time-acceptance in subsamples

1070 Figure E.1 shows the spline coefficients obtained by fitting the decay-time distribution of
 1071 $B_s^0 \rightarrow D_s\pi\pi\pi$ data candidates in different subsamples. Sufficient agreement is observed
 1072 within a given data-taking period, while the acceptance shapes for Run-I and Run-II
 1073 data differ significantly. The fitted splines for the different D_s final states are in a good
 1074 agreement. The largest deviations are observed between the different L0 categories.

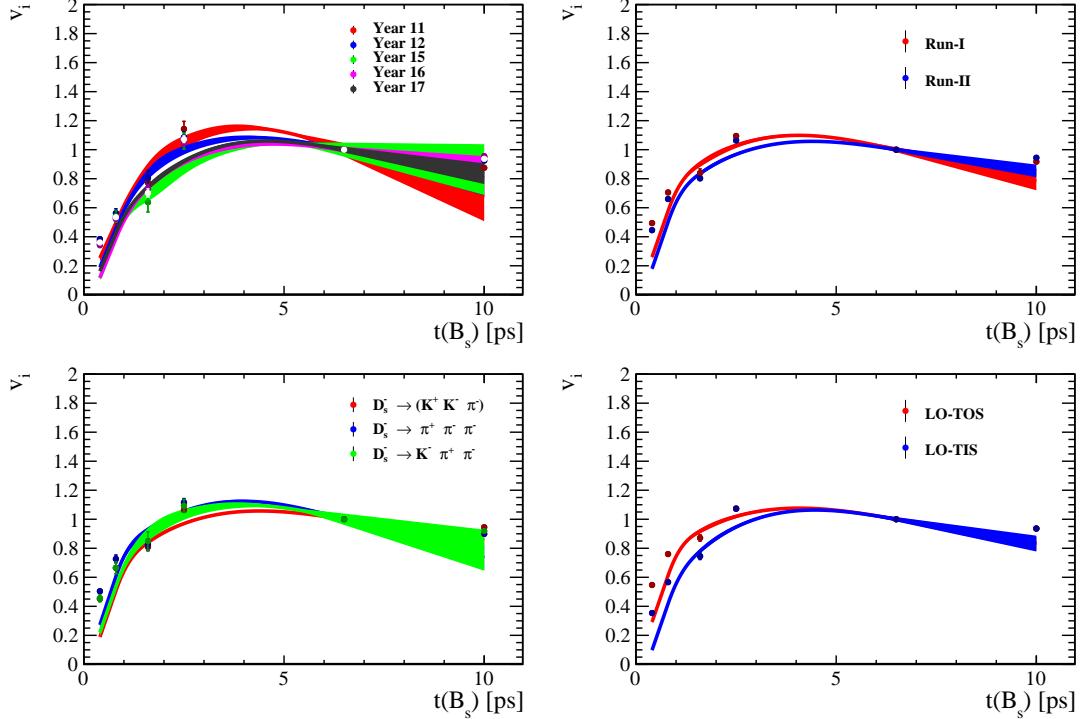

Figure E.1: Comparison of the spline coefficients (point with error bars) obtained from time-dependent fits to the $B_s^0 \rightarrow D_s\pi\pi\pi$ decay-time for different subsamples: (top-left) different years of data-taking; (top-right) different data-taking periods; (bottom-left) different D_s final states; (bottom-right) different trigger categories. The interpolated splines are overlaid.

1075 F Comparison of phase-space acceptance in subsamples

1077 Figures F.1, F.2 and F.3 compare the phase space-acceptance projections obtained from
 1078 $B_s \rightarrow D_s K\pi\pi$ MC in different subsamples. Sufficient agreement is observed between
 1079 different data-taking periods and D_s final states. The largest deviations are observed
 1080 between the different L0 categories.

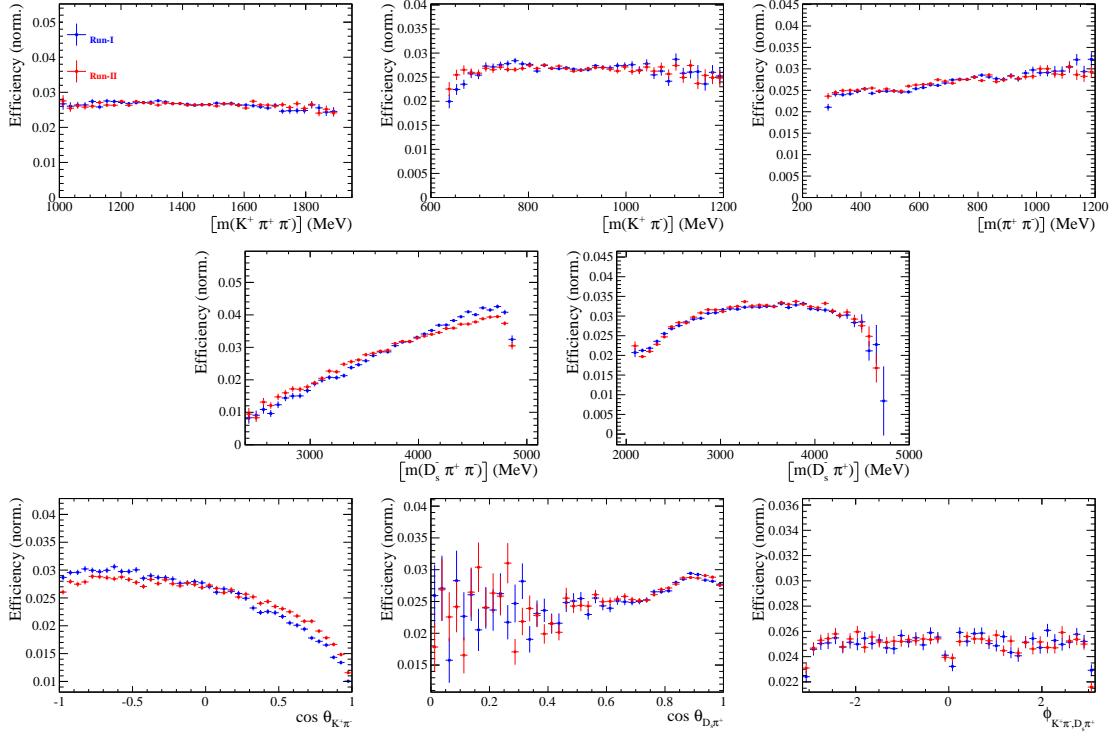

Figure F.1: Comparison of the phase space acceptance for different data-taking periods. A χ^2 -test between the samples yields $\chi^2/\nu = 1.10$ (with $\nu = 533$) using an adaptive 5D binning.

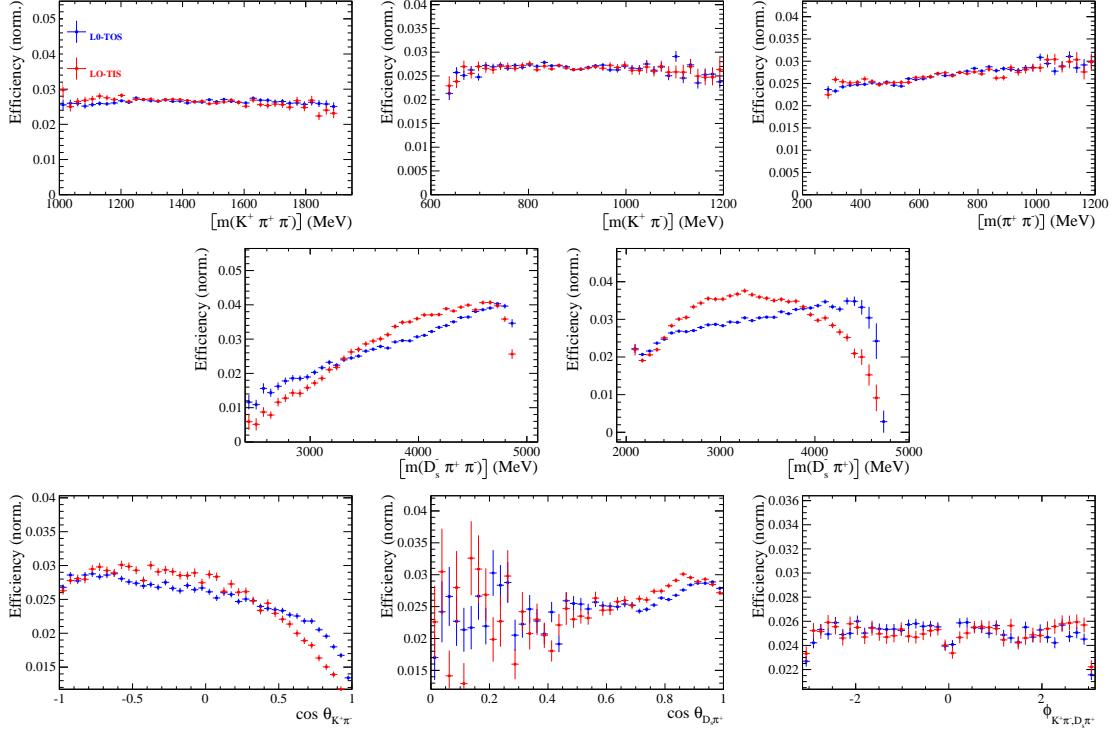

Figure F.2: Comparison of the phase space acceptance for different trigger categories. A χ^2 -test between the samples yields $\chi^2/\nu = 1.62$ (with $\nu = 1211$) using an adaptive 5D binning.

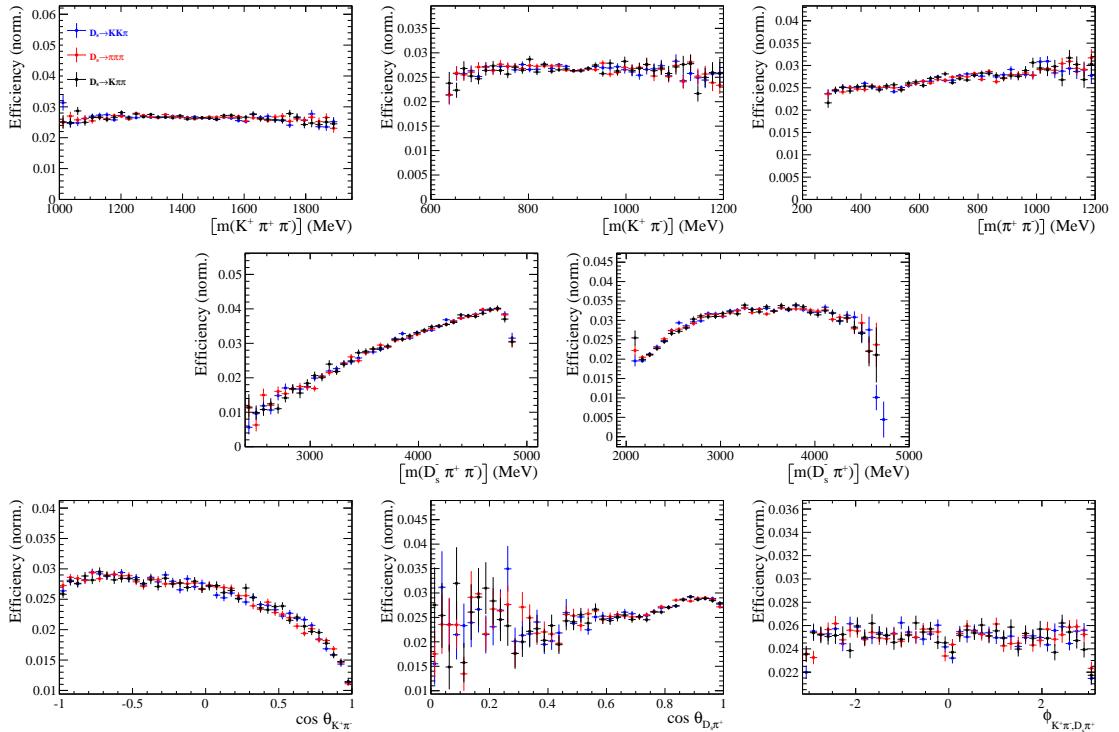

Figure F.3: Comparison of the phase space acceptance for different D_s final states. A χ^2 -test using an adaptive 5D binning between the $D_s \rightarrow KK\pi$ and $D_s \rightarrow K\pi\pi$ samples yields $\chi^2/\nu = 1.01$ (with $\nu = 728$), $\chi^2/\nu = 0.96$ (with $\nu = 988$) between $D_s \rightarrow KK\pi$ and $D_s \rightarrow \pi\pi\pi$ and $\chi^2/\nu = 1.00$ (with $\nu = 728$) between $D_s \rightarrow \pi\pi\pi$ and $D_s \rightarrow K\pi\pi$.

1082 H Spin Amplitudes

1083 The spin factors used for $B \rightarrow P_1 P_2 P_3 P_4$ decays are given in Table H.1.

Table H.1: Spin factors for all topologies considered in this analysis. In the decay chains, S , P , V , A , T and PT stand for scalar, pseudoscalar, vector, axial vector, tensor and pseudotensor, respectively. If no angular momentum is specified, the lowest angular momentum state compatible with angular momentum conservation and, where appropriate, parity conservation, is used.

Number	Decay chain	Spin amplitude
1	$B \rightarrow (P P_1)$, $P \rightarrow (S P_2)$, $S \rightarrow (P_3 P_4)$	1
2	$B \rightarrow (P P_1)$, $P \rightarrow (V P_2)$, $V \rightarrow (P_3 P_4)$	$L_{(1)\alpha}(P) L_{(1)}^\alpha(V)$
3	$B \rightarrow (A P_1)$, $A \rightarrow (V P_2)$, $V \rightarrow (P_3 P_4)$	$L_{(1)\alpha}(B) P_{(1)}^{\alpha\beta}(A) L_{(1)\beta}(V)$
4	$B \rightarrow (A P_1)$, $A[D] \rightarrow (P_2 V)$, $V \rightarrow (P_3 P_4)$	$L_{(1)\alpha}(B) L_{(2)}^{\alpha\beta}(A) L_{(1)\beta}(V)$
5	$B \rightarrow (A P_1)$, $A \rightarrow (S P_2)$, $S \rightarrow (P_3 P_4)$	$L_{(1)\alpha}(B) L_{(1)}^\alpha(A)$
6	$B \rightarrow (A P_1)$, $A \rightarrow (T P_2)$, $T \rightarrow (P_3 P_4)$	$L_{(1)\alpha}(B) L_{(1)\beta}(A) L_{(2)}^{\alpha\beta}(T)$
7	$B \rightarrow (V_1 P_1)$, $V_1 \rightarrow (V_2 P_2)$, $V_2 \rightarrow (P_3 P_4)$	$L_{(1)\mu}(B) P_{(1)}^{\mu\alpha}(V_1) \epsilon_{\alpha\beta\gamma\delta} L_{(1)}^\beta(V_1) p_{V_1}^\gamma L_{(1)}^\delta(V_2)$

1084 I Considered Decay Chains

1085 The various decay channels considered in the model building are listed in Table I.1.

Table I.1: Decays considered in the LASSO model building.

Decay channel
$B_s \rightarrow D_s^- [K_1(1270)^+ [S, D] \rightarrow \pi^+ K^*(892)^0]$
$B_s \rightarrow D_s^- [K_1(1270)^+ \rightarrow \pi^+ K^*(1430)^0]$
$B_s \rightarrow D_s^- [K_1(1270)^+ [S, D] \rightarrow K^+ \rho(770)^0]$
$B_s \rightarrow D_s^- [K_1(1270)^+ [S, D] \rightarrow K^+ \omega(782)]$
$B_s \rightarrow D_s^- [K_1(1400)^+ [S, D] \rightarrow \pi^+ K^*(892)^0]$
$B_s \rightarrow D_s^- [K_1(1400)^+ [S, D] \rightarrow K^+ \rho(770)^0]$
$B_s \rightarrow D_s^- [K(1460)^+ \rightarrow \pi^+ \kappa]$
$B_s \rightarrow D_s^- [K(1460)^+ \rightarrow K^+ \sigma]$
$B_s \rightarrow D_s^- [K(1460)^+ \rightarrow \pi^+ K^*(892)^0]$
$B_s \rightarrow D_s^- [K(1460)^+ \rightarrow K^+ \rho(770)^0]$
$B_s \rightarrow D_s^- [K^*(1410)^+ \rightarrow \pi^+ K^*(892)^0]$
$B_s \rightarrow D_s^- [K^*(1410)^+ \rightarrow K^+ \rho(770)^0]$
$B_s \rightarrow D_s^- [K_2^*(1430)^+ \rightarrow \pi^+ K^*(892)^0]$
$B_s \rightarrow D_s^- [K_2^*(1430)^+ \rightarrow K^+ \rho(770)^0]$
$B_s \rightarrow D_s^- [K^*(1680)^+ \rightarrow \pi^+ K^*(892)^0]$
$B_s \rightarrow D_s^- [K^*(1680)^+ \rightarrow K^+ \rho(770)^0]$
$B_s \rightarrow D_s^- [K_2(1770)^+ \rightarrow \pi^+ K^*(892)^0]$
$B_s \rightarrow D_s^- [K_2(1770)^+ \rightarrow K^+ \rho(770)^0]$
$B_s \rightarrow \sigma^0(D_s^- K^+)_S$
$B_s [S, P, D] \rightarrow \sigma^0(D_s^- K^+)_V$
$B_s \rightarrow \rho(770)^0(D_s^- K^+)_S$
$B_s [S, P, D] \rightarrow \rho(770)^0(D_s^- K^+)_V$
$B_s \rightarrow K^*(892)^0(D_s^- \pi^+)_S$
$B_s [S, P, D] \rightarrow K^*(892)^0(D_s^- \pi^+)_V$
$B_s \rightarrow (D_s^- K^+)_S (\pi^+ \pi^-)_S$
